

GATE-TRIAGE

Gate triage — sweep failures

Field	Value
Revision	2
Created	2026-08-27
Last modified	2026-09-02
Status	active
Status summary	Triage of every FAIL reported by scripts/ verify-all-constitution-rules.sh. §1–§8 are the 2026-08-27 triage of a 58-gate sweep at the PRE-fast-forward constitution and are SUPERSEDED — they are kept because the reasoning is still sound and the arithmetic in §3.1 is still instructive, not because the numbers are current. <u>§9 is the current</u> <u>measurement</u>: the first sweep to run to completion after the constitution was fast- forwarded, 186 PASS / 95 FAIL / 6 ERROR of 287 gates, exit 1, triaged into (a) third- party & staged carriers, (b) constitution- internal defects, (c) genuinely ours. No verdict was suppressed, allowlisted or downgraded in either round.
Sweep under triage	scripts/verify-all-constitution-rules.sh — 58 gates in §1–§8; 287 gates in §9 448981ae3498229c734dc60719f4b19f01d7a75f
Constitution HEAD	in §1–§8; f5876a3b700eb9a8792c1f19baca77959a2a7e88 in §9
Scope	

Field	Value
	Triage only. No submodule working tree was written to. No mutating git command was run. §1–§8 additionally carried one comment-accuracy correction in the umbrella’s own sweep script.

§11.4.65 disclosure. This document ships without its .html and .pdf siblings — the same known, disclosed deviation INVENTORY.md records as gap **G8**. Stated rather than left to be discovered.

Reading order (§11.4.6). The document’s original H1 was “*the 21 sweep failures*”. That title is now wrong — the completed post-fast-forward sweep reports 95 FAIL and 6 ERROR — so it was corrected rather than left to mislead a reader who stops at the heading. **Every count in §1–§8 is withdrawn as a statement about the present tree**; not one of them is comparable to §9, because the gate population moved 57 → 286 when the constitution submodule was fast-forwarded. §1–§8 remain readable as the record of a different, earlier corpus.

1. How the sweep was run

```
bash scripts/verify-all-constitution-rules.sh 2>&1 | tee /tmp/sweep.txt
```

Every failing gate was then re-run **directly**, with the argv the gate’s own usage header dictates. --root means three different things across this family, and passing the wrong one produces a false verdict in *both* directions — verified, not assumed:

Gate family	Header says	Correct root
cm_covenant_114*_propagation.sh	--root <consumer-root>	repo root
cm_continuum_resume_engine_present.sh, cm_gate_ledger_ratchet.sh	--root <constitution-root>	submodules/ constitution
cm_track_branch_label*.sh	no --root	gate defaults

Gate family	Header says	Correct root
lib/pointer_carrier.sh	—	--selftest
gate_ledger.sh	—	selfcheck <scratchdir>

Proof that the root matters (both runs are read-only):

```
$ bash submodules/constitution/scripts/gates/
cm_covenant_114_162_propagation.sh --root submodules/constitution
CM-COVENANT-114-162-PROPAGATION: 4 PRESENT, 7 POINTER-INHERITANCE-
SKIP, 0 MISSING (anchor 11.4.162)
    CM-COVENANT-114-162-PROPAGATION: PASS – every owned carrier
carries §11.4.162      <-- FALSE PASS

$ bash submodules/constitution/scripts/gates/
cm_continuum_resume_engine_present.sh --root .    ; echo rc=$?
    MISSING engine directory: submodules/continuum (expected under
.../vasic)
rc=1
<-- FALSE FAIL
```

The sweep resolves both correctly — its --list output prints every resolved argv, and it matches the table above for all 57 discovered gates plus the project-side inheritance test.

gate_ledger.sh — the sweep handles it correctly

gate_ledger.sh is a multi-subcommand tool, not a gate with a default action. The sweep detects its selfcheck) branch and invokes bash gate_ledger.sh selfcheck <scratch> — confirmed in the run log:

```
PASS    rc=0          679ms  gate_ledger.sh
selfcheck <scratch>
```

Two corrections to the premise, both verified on 2026-08-27:

- Invoked **bare**, gate_ledger.sh exits **2**, not 0 (usage >2; exit 2). Under this sweep an rc=2 scores **ERROR** — “a blind instrument, never a pass” (§11.4.201(7)(b)) — so a bare invocation could not have produced a false PASS here either. It still proves nothing, so using the documented self-test is right regardless.
- The sweep’s own header comment claimed the bare exit was 0. That claim was false. It is corrected in §4 below.

lib/pointer_carrier.sh --selftest is a real 5-fixture golden test, not a formality: pointer_carrier.sh selftest: PASS (5/5), including the two decoys (mid-line backticked heading, ~~~~fenced heading) that would otherwise let a non-pointer carrier be silently skipped.

2. Before — the sweep as found

```
*
gates run          : 58
  PASS            : 37
  FAIL   (rc=1)    : 21
  ERROR  (rc!=0,1) : 0
$11.4.32 step 1    : skip
  SWEEP: FAIL - 21 FAIL + 0 ERROR out of 58 gate(s).
```

The 21 are exactly: the 17 cm_covenant_114*_propagation.sh gates, plus cm_continuum_resume_engine_present.sh, cm_gate_ledger_ratchet.sh, cm_track_branch_label.sh, cm_track_branch_label_mutation_test.sh.

Verified, not assumed: the 17 propagation gates emit **85 MISSING lines** in total, and those 85 resolve to exactly **five distinct carriers** ($17 \times 5 = 85$, no sixth carrier anywhere):

```
$ grep -c "    MISSING" /tmp/sweep.txt
85
$ grep "    MISSING" /tmp/sweep.txt | sed 's/.*MISSING *//; s/ *
- .*/' | sort -u | wc -l
5
```

All 17 report the identical shape: 4 PRESENT, 11 POINTER-INHERITANCE-SKIP, 5 MISSING, and the five fence-aware ones (230/231/232/233/235) additionally report 0 DIVERGENT — i.e. **no carrier holds a corrupted or duplicated anchor block**; the only defect is absence.

3. The 21 rows

Category key — **(a)** fixable inside this umbrella repo · **(b)** requires writing into a submodule working tree (operator decision, push blast radius) · **(c)** genuinely upstream / third-party, not ours.

The 17 propagation gates are **mixed (b + c)**: each one is held FAIL by five carriers at once — one owned-submodule carrier (b) and four third-party carriers (c). Clearing the (b) carrier alone does **not** flip any of them.

#	Gate	^x Exact failing assertion (quoted from its own output)	File(s) named
1	cm_covenant_114_162_propagation.sh	CM- COVENANT-114-162- PROPAGATION: FAIL – 5 owned carrier(s) missing §11.4.162 anchor ^x — MISSING <carrier> – lacks anchor literal 11.4.162 ×5	the five carriers o

Row-level counts: (a) 0 · pure (b) 4 · pure (c) 0 · mixed (b + c) 17.

Root-cause counts (the five carriers behind rows 1–17, plus the three constitution-internal defects behind rows 18–21): **(a) 0 · (b) 4 · (c) 4.**

3.1 The five carriers behind rows 1–17

Carrier	Lives in	Owning repo	Cat.	Why it is not an umbrella fix
milosvasic.ru/ Upstreamable/ AGENTS.md	gitlink inside the milosvasic.ru submodule	red-elf/Upstreamable (milosvasic.ru/.gitmodules:3)	c	Third-party, two levels down. The project neither nor pushes it.
milosvasic.ru/ Upstreamable/ CLAUDE.md	same	red-elf/Upstreamable	c	same
submodules/ superspec/ examples/ static- landing-page/ CLAUDE.md	submodules/ superspec submodule	WangX0111/superspec	c	Third-party. A demo fixture the points at specs static-landing plan.md; it is no governance can is only <i>named</i> one.
.specify/ extensions/ superspec/ examples/ static- landing-page/ CLAUDE.md	umbrella working tree (git ls-files tracks it)	vendored copy of WangX0111/superspec v1.0.2	c	Physically written here — deliberately not written. It of 59 tracked files a vendored third party spec-kit extension (.spec extensions/.re pins manifest_ sha256:6e23ee6 byte-identical to submodule copy Injecting 17 constitution and blocks into a third party demo fix would fork the vendored artifact from its upstream and invalidate manifest hash, satisfy a gate the misreading a demo file as a govern

Carrier	Lives in	Owning repo	Cat.	Why it is not an umbrella fix
vasic.digital/ QWEN.md	vasic.digital submodule	vasic-digital/vasic- digital.github.io — owned	b	carrier. Record a non-fix, not a impossibility. The only owner Requires writing a submodule working tree a push that rede live GitHub Pa site — see §6.

Note the arithmetic that decides rows 1–17: even if the operator applies the (b) fix to vasic.digital/QWEN.md, **four (c) carriers remain and all 17 gates still FAIL**. There is no umbrella-side change that flips any of the 21.

4. What was actually fixed

One change, in the umbrella repo, verdict-neutral.

scripts/verify-all-constitution-rules.sh — the header comment describing how gate_ledger.sh is invoked stated that a bare invocation “prints its usage and exits 0, which would be a false PASS”. Measured behaviour is exit 2. Under this sweep rc=2 scores ERROR (§11.4.201(7) (b)), never PASS, so the comment misdescribed both the exit code and the hazard it was warning about. §11.4.6 forbids leaving a verified-false statement in place. The comment now reads:

```
# 2. Else if it offers a `selfcheck)` subcommand -> run
`selfcheck <tmpdir>`.
# (`gate_ledger.sh` is a multi-subcommand tool: invoked bare
it prints its
# usage and exits 2 – verified 2026-08-27 – so the sweep
would score it
# ERROR (a blind instrument, §11.4.201(7)(b)), never PASS.
Either way a
# bare invocation proves nothing, so its documented self-test
is used
# instead.)
```

bash -n scripts/verify-all-constitution-rules.sh → clean.
Executable logic untouched: the resolution branch it documents (grep -qE '^[[:space:]]*selfcheck\)' is unchanged, and gate_ledger.sh still runs as selfcheck <scratch>.

Nothing else was changed. In particular:

- No submodule working tree was written to.
 - No mutating git command was run (no add/commit/push/fetch/checkout/submodule update).
 - The four root carriers CLAUDE.md / AGENTS.md / QWEN.md / GEMINI.md were **not** modified by this triage — no fix required it. §11.4.157 lockstep verified twice with tail -n +24 <f> | sha256sum: d26e2c31252d8837... for all four at the start of the triage, 961f47134720080e... for all four at the end. The bodies changed under this task — an edit from work outside it, visible as 9 ++-- on each of the four plus one line of Constitution.md in git status. All four moved together, so the lockstep held; it is recorded here because a reader comparing digests would otherwise think this task moved them.
 - No gate verdict was suppressed, allowlisted or downgraded.
-

5. After — the sweep re-run

```
gates run          : 58
  PASS             : 37
  FAIL   (rc=1)    : 21
  ERROR  (rc!=0,1) : 0
§11.4.32 step 1    : skip
  SWEEP: FAIL - 21 FAIL + 0 ERROR out of 58 gate(s).
```

Sweep exit code: 1. The failure **set** is byte-identical to the before run, not merely the same size:

```
$ diff <(sed -n '/^FAILED:$/,/^$/p' /tmp/sweep.txt) \
      <(sed -n '/^FAILED:$/,/^$/p' /tmp/sweep-after.txt) && echo
IDENTICAL
IDENTICAL
$ grep -c "  MISSING" /tmp/sweep-after.txt
85
```

Before → after: 37 PASS / 21 FAIL / 0 ERROR → 37 PASS / 21 FAIL / 0 ERROR. Unchanged, and that is the correct outcome: every one of the 21 is blocked behind a submodule write or a third-party repository. A number that improved here would have meant a verdict was gamed.

6. Requires operator decision — the category (b) items

Each item below needs a write into a submodule working tree and a push. The push fan-out is stated because it is the real cost of the decision.

6.1 vasic.digital/QWEN.md — blocks rows 1–17 (partially)

- **Change:** give vasic.digital/QWEN.md the 17 anchors (or make it a genuine §11.4.35 pointer consumer so the propagation gates skip it).
- **Push blast radius:** vasic.digital — origin, github, upstream all fetch **and** push the single URL git@github.com:vasic-digital/vasic-digital.github.io.git. **One distinct URL — and it is a live GitHub Pages site: a push redeploys the site.**
- ⚠ **The staged fix does not do what the record claims.**
Constitution.md → “Known-excluded gate findings” says the fix “is staged at docs/constitution-adoption/propagation/vasic.digital/QWEN.insert-block.md”. Read as staged, it would **not** clear a single propagation gate:
 - QWEN.insert-block.md contains **none** of the 17 anchor literals (11.4.162, 11.4.167, ... 11.4.235) — it cites only §11.4.28.
 - It opens > ****Base agent rules:**** ..., a blockquote — **not** a real, non-fenced, line-anchored **## INHERITED FROM** heading — so `is_pointer_carrier()` will not recognise it and the gates will not skip the file.
 - Worse, APPLY.md §4.6 also copies AGENTS.md.staged, CLAUDE.md.staged and GEMINI.md.staged into vasic.digital/. Those three open **# CLAUDE.md – vasic.digital / ## Helix Constitution inheritance** — again not **## INHERITED FROM**. Applying §4.6 as written would create **three new discovered carriers that also lack every anchor**, taking the fleet from 5 MISSING carriers to 8 and the total from **85 MISSING lines to 136**. The 17 gates would still FAIL, louder.
 - **Operator action required before applying §4.6:** either add the anchors to all four vasic.digital carriers, or restructure them to start with a real **## INHERITED FROM** heading. Applying the staged files unchanged makes the sweep worse.

6.2 cm_continuum_resume_engine_present.sh — row 18

- **Change:** remove the single ATMOSphere literal from the resume engine — submodules/constitution/submodules/continuum/test/e2e/e2e_test.go:118: b, err := resume.Render(fresh, "", resume.Options{Title: "ATMOSphere fleet resume"}). The gate's denylist is atmosphere|rockchip|kinopoisk|orange[[:space:]]*pi|mmt/track; this is the only hit in the whole engine. Everything else in the gate passes, including go test -race ./... and the continuum selfcheck.
- **Push blast radius:** submodules/constitution/submodules/continuum — origin only, git@github.com:vasic-digital/continuum.git. **One URL.** A **nested** submodule (a gitlink of submodules/constitution), so landing it also bumps the constitution's gitlink → §6.4's 6-URL fan-out.

6.3 cm_track_branch_label.sh + its mutation test — rows 20 and 21

- **Root cause (a real defect, not an environment quirk):** the reference labeler submodules/constitution/scripts/multitrack/track_branch_label.sh:268 now emits a **five**-field label — printf '(T%s/%s - %s - %s - %s)\n' "\$_n" "\$_br" "\$_al" "\$_mo" "\$_ef" → (T1/main - cmgatechk - ? - xhigh) — while the gate's helper _label_alias() (cm_track_branch_label.sh:91-97) still extracts the alias with \${_p##* - }, i.e. the **last** field. It therefore reads the *effort* (xhigh) where it expects the *alias* (cmgatechk). This is unconditional: whatever the effort field resolves to, the last field is never the alias. The gate/labeler pair drifted apart; the gate was not updated when the label grew model + effort fields.
- **Change:** in _label_alias(), select the alias **positionally** (field 2 of the --separated label) instead of taking the trailing field.
- **Row 21 is a consequence, not an independent defect.** The mutation test's own output proves it: its two META FAIL lines are both on the *clean* and the *RESTORED* fixtures ("gate FAILED unexpectedly (false alarm!)", while all three genuine mutations were caught (META OK ×3). The discriminator is intact; it fails only because the gate it audits false-alarms. Fixing #20 fixes #21.
- **Push blast radius:** submodules/constitution — see §6.4.

6.4 cm_gate_ledger_ratchet.sh — row 19

- **Change:** inside submodules/constitution, either land the ~12 missing gate implementations, register their deferrals in scripts/gates/gate_ledger_deferrals.tsv against tracked items, or make an explicit, reviewable commit raising scripts/gates/gate_ledger_baseline.txt from 420. Every input — Constitution.md, scripts/, and the three registries — lives inside the submodule.
Nothing in the umbrella can move this number.
- **Push blast radius:** submodules/constitution — origin **pushes to 6 URLs** in one command: git@gitflic.ru:helixdevelopment/helixconstitution.git, git@github.com:HelixDevelopment/HelixConstitution.git, git@gitlab.com:helixdevelopment1/helixconstitution.git, git@gitverse.ru:helixdevelopment/HelixConstitution.git, git@github.com:vasic-digital/HelixConstitution.git, git@gitlab.com:vasic-digital/HelixConstitution.git. Rows 18, 19, 20 and 21 all land here, and each one changes the constitution every consuming project inherits.

6.5 For completeness — other owned submodules named in APPLY.md

Not implicated in any of the 21 failures, but the same operator decision governs them, and their fan-out is larger:

- monetization — origin **pushes to 4 URLs**:
git@gitflic.ru:milosvasic/monetization.git,
git@github.com:milos85vasic/monetization.git,
git@gitlab.com:milos85vasic/monetization.git, ssh://
git@gitverse.ru:2222/milosvasic/monetization.git.
 - milosvasic.ru — origin **pushes to 2 URLs** it does **not** fetch from (gitflic.ru:milosvasic/milosvasic-net-v-2, github.com:milos85vasic/milosvasic.net.v2), while fetching from a third that receives nothing. That fetch/push asymmetry is already recorded in Constitution.md as an open operator decision.
-

7. Category (c) — upstream / third-party, not ours

Item	Repo	Where it would have to be fixed
milosvasic.ru/ Upstreamable/ AGENTS.md	red-elf/Upstreamable	upstream, a gitlink of a submodule
milosvasic.ru/ Upstreamable/ CLAUDE.md	red-elf/Upstreamable	upstream, same
submodules/ superspec/examples/ static-landing-page/ CLAUDE.md	WangX0111/superspec	upstream
.specify/extensions/ superspec/examples/ static-landing-page/ CLAUDE.md	vendored WangX0111/ superspec v1.0.2	upstream — writable here, deliberately not written (see §3.1)

The more durable fix for all four is **upstream in the gate family**, per §11.4.26: the propagation gates discover carriers by bare filename and prune only `node_modules|.git|out|build|dist|prebuilts|external|vendor|target`. A third-party submodule tree and a vendored extension's demo fixture are neither owned nor governance carriers, yet both are scored as owned carriers. Any in-repo workaround for that would be an allowlist, which this triage will not write.

8. False failures and false passes found

8.1 No false failure among the 21

All 21 were reproduced by hand, with the argv each gate's own usage header dictates. Every failing assertion is a true statement about the tree. Two false-verdict *hazards* exist but the sweep avoids both:

- **Wrong --root → false PASS.** `cm_covenant_114_162_propagation.sh --root submodules/constitution` reports 0 MISSING and exits 0, because it then only sees the constitution's own carriers. The sweep passes the repo root.

- **Wrong --root → false FAIL.**

cm_continuum_resume_engine_present.sh --root . reports the engine, go.mod and helix-deps.yaml all MISSING and exits 1. The sweep passes submodules/constitution.

Every gate that accepts --root declares its kind in its usage header — checked across all 57 — so the sweep’s header-driven resolution has no undeclared case to fall through on.

8.2 CM-OPENDESIGN-UI-SYSTEM is a false PASS

```
PASS rc=0 cm_opendesign_ui_system.sh --root /run/media/.../vasic
SKIP CM-OPENDESIGN-UI-SYSTEM: no UI surface detected under
.../vasic
(no theme/token/visreg sources matched OD_*_GLOBS) – §11.4.3
SKIP-with-reason, not a fake PASS
```

The skip **reason is factually false for this repository**. There is a real UI surface — design-system/learning-kit/kit-tokens.css, design-system/brand-vasic-digital/vasic-digital.css, design-system/brand-milosvasic/milosvasic.css, design-system/components-extended.css, design-system/motion/*.css, design-system/fonts/fonts.css. The gate’s defaults

(OD_THEME_GLOBS="src/theme/* src/styles/* styles/* theme/* ...", OD_TOKEN_GLOBS="tokens.json design-tokens/* ...") simply do not describe this repo’s layout, and the umbrella never binds OD_*_GLOBS. The gate is therefore scored PASS while never having looked at the design system §11.4.162 governs.

Not changed here, for two reasons: it is not one of the 21 under triage, and binding OD_*_GLOBS would turn a PASS into a FAIL — the honest direction, but a scope and configuration decision for the operator, not a silent edit. Recorded as the outstanding action.

8.3 The “37 PASS” figure includes 3 reasoned SKIPS

Three gates exit 0 via an explicit §11.4.3 skip and are counted as PASS, because the sweep’s SUMMARY has no SKIP column:

Gate	Skip reason	Honest
cm_build_on_source_proven_not_test_side.sh	feature_disabled_by_config: no consumer marker-binding config	yes — t feature genuine is unbour

Gate	Skip reason	Honest
cm_version_increment_on_deploy.sh	feature_disabled_by_config: no consumer deploy-ledger binding	yes — same
cm_opendesign_ui_system.sh	no UI surface detected	no — s §8.2

So 37 PASS is more precisely **34 enforced PASS + 2 honest unbound-feature SKIPS + 1 false SKIP**. Adding a SKIP column to the sweep’s summary would make the sweep’s own reporting §11.4.6-honest; it is a reporting change with no verdict impact, and is left as an operator call alongside §8.2.

8.4 The Constitution.md “staged fix” claim is optimistic

Section 6.1 above. The record says the vasic.digital/QWEN.md fix “is staged and awaits operator application”; the staged artefact would not clear the gates, and applying APPLY.md §4.6 unchanged would raise the MISSING count from 85 to 136. This is the one item in the existing record that a reader could act on and be worse off for.

9. 2026-09-02 — the first completed post-fast-forward sweep

Everything above this line describes a **58-gate** sweep against the pre-fast-forward constitution. This section is the first sweep to **run to completion** after the fast-forward, and it supersedes §1–§8 entirely.

9.1 How it was run

```
bash scripts/verify-all-constitution-rules.sh > <scratch>/  
sweep-2026-09-02.txt 2>&1
```

No flags. No --quiet. Nothing silenced, nothing narrowed. The run was launched detached and polled to completion; wall clock $\approx$ **2 h 45 min**, output **718,345 lines / 105,209,937 bytes** (see §9.6 — 714,162 of those lines come from a single gate that was pointed at the wrong tree).

Evidence file, preserved: <scratch>/sweep-2026-09-02.txt under /tmp/.private/milosvasic/claude-1000/-run-media-milosvasic-DATA4TB-Projects-vasic/8b2dcbd5-36ee-4998-811b-54668193abff/scratchpad/.

9.2 The exact split

Quoted verbatim from the run's own SUMMARY block (lines 3305–3312):

```
gates run          : 287
  PASS             : 186
  FAIL    (rc=1)    : 95
  ERROR   (rc!=0,1) : 6
§11.4.32 step 1    : pass
```

Closing line and exit code, verbatim:

```
SWEEP: FAIL – 95 FAIL + 6 ERROR out of 287 gate(s).
EXIT_CODE=1
```

- **287 gates** = 286 discovered dynamically under submodules/
constitution/scripts/gates/** + 1 project-side tests/
test_constitution_inheritance.sh (which **PASSEd**, 8 PASS / 0 SKIP /
0 FAIL).
- **§11.4.32 step 1 = pass** — scripts/verify-governance-cascade.sh
returned rc=0 inside the sweep. Step 1 is no longer a SKIP; OC-3
stays resolved.
- **Constitution HEAD at run time: f5876a3b700eb9a8792c1f19baca779
59a2a7e88**, as the sweep's own header line records.

The pin moved under this measurement, and that is stated rather than hidden (§11.4.6). Re-measured immediately after the run, `git -C submodules/constitution rev-parse HEAD` returns **3be10826f3d236edcdb62b7cba81cda4e6d0d47a** — a different commit from the f5876a3b700e the sweep ran against, and different again from the f16ea779b82a the root carriers record. Concurrent work moved the gitlink while this sweep was running. **The split in §9.2 is a measurement of f5876a3b700e and of nothing else;** a re-run today may differ, and the honest response is to re-run, not to quote this number as standing fact.

The prior figure on record — “*186 PASS / 95 FAIL / 6 ERROR of 287 gates*”, carried in the root carriers as a **reported prior measurement** from a run that never finished — is now **CONFIRMED by a completed run**. It was accurate. It is no longer a report of somebody else's number.

9.3 The three buckets

Row-level assignment — each of the 101 non-PASS rows gets exactly one primary bucket, so nothing is double-counted:

Bucket	Rows	Of which FAIL	Of which ERROR
(a) third-party and staged carriers	82	82	0
(b) defects internal to the constitution submodule	5	4	1
(c) genuinely ours	14	9	5
Total	101	95	6

Four of the fourteen (c) rows are **mixed (b + c)** and are counted in (c) deliberately — see §9.5 item **C6**: an upstream path-derivation defect points them at the wrong directory, *and* the artifact they look for does not exist at the right directory either, so clearing the upstream half alone would not flip any of them.

Neither (a) nor (b) licenses treating this sweep as green. Both classes still FAIL, both still make the sweep exit 1, and both are still printed in full. Excluded from `verify-governance-cascade.sh`'s own verdict means *not double-counted there, never suppressed anywhere* (§11.4.6).

9.4 Bucket (a) — third-party and staged carriers · 82 rows

Every one of the 82 rows is a `cm_covenant_114_<N>_propagation.sh` gate. Run at the correct root, each reports the **identical shape** and is held FAIL by **exactly five carriers**, none of which any commit in this repository can change:

#	Carrier	Owning repository	Why it is not ours
1	<code>milosvasic.ru/Upstreamable/AGENTS.md</code>	<code>red-elf/Upstreamable</code>	third-party, a gitlink inside the <code>milosvasic.ru</code> submodule —

#	Carrier	Owning repository	Why it is not ours
			two levels down
2	milosvasic.ru/ Upstreamable/ CLAUDE.md	red-elf/ Upstreamable	same
3	submodules/ superspec/ examples/ static- landing-page/ CLAUDE.md	WangX0111/ superspec	third-party; a 5-line demo fixture only <i>named</i> like a governance carrier
4	.specify/ extensions/ superspec/ examples/ static- landing-page/ CLAUDE.md	vendored WangX0111/ superspec v1.0.2	tracked here and physically writable — deliberately not written (§3.1 of this document explains why: it would fork the vendored artifact from upstream and invalidate its manifest hash)
5	workshop/ pipeline/ engines/ whisper.cpp/ AGENTS.md	upstream whisper.cpp	NEW since the 2026-08-27 triage — the vendored whisper.cpp build tree inside the private workshop submodule. It is a third-party inference engine's own repository file, not a governance

#	Carrier	Owning repository	Why it is not ours
			carrier; it was pulled in when the ASR stack was built

Measured, quoted from the one propagation gate the sweep argv-resolved correctly (cm_covenant_114_167_propagation.sh):

CM-COVENANT-114-167-PROPAGATION: 4 PRESENT, 64 POINTER-INHERITANCE-SKIP, 5 MISSING
(anchor 11.4.167) under <ext-volume-host>/Projects/vasic

and re-derived independently for a fence-aware member of the family (cm_covenant_114_162_propagation.sh --root <repo>):

CM-COVENANT-114-162-PROPAGATION: 4 single-block-PRESENT, 64 POINTER-INHERITANCE-SKIP,
5 MISSING/DUPLICATED, 0 DIVERGENT (anchor 11.4.162) under /run/media/.../vasic

0 DIVERGENT — no carrier holds a corrupted or duplicated anchor block. The only defect in this family is absence.

One real improvement since 2026-08-27, measured not assumed:
vasic.digital/QWEN.md — the single *owned* carrier §3.1 named as the lone category-(b) gap — **no longer appears in any MISSING list**. The owned half of the propagation problem is closed; what remains is entirely third-party. The POINTER-INHERITANCE-SKIP count also moved 11 → 64 as the fleet grew and the new carriers were authored as genuine §11.4.35 pointer consumers.

9.5 Bucket (b) — internal to the constitution submodule · 5 rows

Upstream code this repository consumes rather than owns. **No commit made here can clear any of these.**

#	Gate	Verdict	The defect, quoted from its own output
1	cm_continuum_resume_engine_present.sh	FAIL	FOUND project-specific literal(s) inside the engine (decoupling

#	Gate	Verdict	The defect, quoted from its own output
2	cm_opendesign_ui_system_mutation_test.sh	FAIL	violation): naming submodules/ continuum/pkg/chair exec_call_test.go and submodules/ continuum/test/e2e/ e2e_test.go. Everything else in the gate passes (go test -race ./... race-clean; continuum selfcheck good=PASS bad=FAIL negctrl=PASS). Two files now, not one — §6.2 of this document recorded only ^xe2e_test.go. Both live in a <i>nested</i> gitlink of the constitution. META FAIL: propagation gate / clean fleet – gate FAILED on a clean fixture (false alarm!). Three of its four meta-assertions pass. This is a §11.4.201(1) false-positive refusal inside the constitution’s own §1.1 mutation pair — the gate accuses a clean fixture. [FAIL] baseline DRV A4-NAME-COLLISION- AMBIGUOUS = ABSENT_ID – a mutation cannot be
3	cm_dependency_register_verdicts_mutation_test.sh	FAIL	

#	Gate	Verdict	The defect, quoted from its own output
4	cm_instrument_trap_scan_mutation_test.sh	FAIL	shown to flip an assertion that is not passing to begin with, and the same for DRV-A2, DRV-A3, DRV-A5. The mutation test cannot establish a surgical control because its own gate has no consumer register to assert against (§9.5 C6). PAIR-NOT-DEMONSTRATED: required file absent: .../submodules/scripts/testing/anti_slop/us2_trap_scan_red.s SELFTEST-BLIND fixtures not found at .../scripts/gates/lib/../../../../scripts/testing/anti_slop/fixtures/traps – reporting blindness, not compliance. The ../../../../ walk assumes the constitution sits at <consumer>/constitution; this repository places it at <consumer>/submodules/constitution, so the walk lands one level short. Honest of the gate to report blindness rather
5	lib/instrument_trap_scan.sh	ERROR rc=2	

#	Gate	Verdict	The defect, quoted from its own output
			than pass — the defect is the hardcoded walk, and it is upstream.

9.6 Bucket (c) — genuinely ours · 14 rows

This is the actionable output. Every item below names the gate, the file, and what it would take to fix.

C1 — resolve_argv in our own sweep points 85 of 287 gates at the WRONG TREE — FIXED 2026-09-02, see the block at the end of this item

This is the largest finding in the run, and it is entirely ours.

- **Gate(s) affected:** 81 cm_covenant_114*_propagation.sh + cm_oracle_strategy_named_and_independent.sh + cm_test_mock_pid_explicit_int.sh + cm_dangerous_combination_fail_closed.sh + cm_killpg_pgid_guard.sh = **85 gates**.
- **File:** scripts/verify-all-constitution-rules.sh, resolve_argv(), lines 199–219.

What happens. With no --root resolved, each gate falls back to its own default consumer root — root="\${CONSUMER_ROOT:-..}" in lib/covenant_propagation_engine.sh:182 — and .. from the sweep's cwd is **<ext-volume-host>/Projects, the parent of this repository:** the operator's entire projects directory, dozens of unrelated repositories.

Two distinct sub-defects, both in our resolver:

- **C1a — the header lookup is gated behind a case-branch grep.** resolve_argv only consults a gate's usage header *after* grep -qE '^[[[:space:]]*--root\)' "\$g" succeeds. The propagation family was refactored upstream into **thin wrappers** (§11.4.251 role-as-data-pack): 61 lines each, arg parsing delegated to the sourced lib/covenant_propagation_engine.sh, so **no --root) branch exists in the wrapper file** — even though its usage header plainly says --root <consumer-root>. Measured: grep -c '\s*--root)' returns **0** for cm_covenant_114_162_propagation.sh (61 lines) and **1** for the one

non-wrapper `cm_covenant_114_167_propagation.sh` (127 lines) — which is exactly why 81 of 82 got no root and one did.

- **C1b — the root_kind case has an unhandled vocabulary.** The case handles constitution-root and consumer-root|project-root only. `cm_oracle_strategy_named_and_independent.sh` and `cm_test_mock_pid_explicit_int.sh` both declare `--root <dir>`, which falls through to `*) argv=""` and takes the gate's default.

Measured consequences — four separate harms, none of them hypothetical:

1. 81 propagation gates FAIL with ZERO BYTES of output.

Reproduced directly:

```
$ bash submodules/constitution/scripts/gates/
cm_covenant_114_162_propagation.sh
rc=1  output_bytes=0          # stdout AND stderr both empty
```

The engine dies under `set -euo pipefail` mid-scan of the parent directory — it has no `exit 1` path of its own (`grep -nE 'exit [0-9]'` engine returns one line, an `exit 2`). A silent `rc=1` is scored **FAIL** by the sweep, i.e. **a blind instrument is being reported as an accusation against this tree** — the §11.4.201(7)(b) hazard, inverted.

2. `cm_test_mock_pid_explicit_int.sh` is a FALSE FAIL. At the correct root it PASSES:

```
$ bash ../cm_test_mock_pid_explicit_int.sh --root /run/media/.../
vasic
rc=0
    CM-TEST-MOCK-PID-EXPLICIT-INT: PASS – every '.pid'-read
Mock/MagicMock/AsyncMock
    in scanned test files sets '.pid' explicitly as an int
 (§11.4.263)
```

A §11.4.201(1) false-positive refusal produced by our own instrument.

3. `cm_oracle_strategy_named_and_independent.sh` emitted 714,162 lines — the 105 MB in §9.1 is almost entirely this one gate reading unrelated projects. At the correct root it emits 15,156 and reaches a verdict about *this* tree (see C5).

4. Two gates hit the 900 s GATE_TIMEOUT and scored ERROR rc=124 — `cm_dangerous_combination_fail_closed.sh` and `cm_killpg_pgid_guard.sh`. Both detail blocks open with `find: '<ext-volume-host>/Projects/proxy/cache/squid/00': Permission denied,`

which is the direct proof they were walking the parent tree. They are ERRORS because the wrong tree is enormous, not because anything here is wrong.

Proof the diagnosis is right, not merely plausible:

```
$ CONSUMER_ROOT=/run/media/.../vasic bash .../  
cm_covenant_114_162_propagation.sh  
rc=1 lines=76  
CM-COVENANT-114-162-PROPAGATION: 4 single-block-PRESENT, 64  
POINTER-INHERITANCE-SKIP,  
5 MISSING/DUPLICATED, 0 DIVERGENT (anchor 11.4.162) under /run/  
media/.../vasic
```

Zero bytes → a full, readable, correctly-scoped verdict.

The fix (three lines of our own script, no submodule write):

1. In `resolve_argv`, consult the gate's **usage header first** — the `grep -oE -- '--root <[a-z-]+>'` lookup already exists; **ungate it** from the `--root)` case-branch `grep` so a thin wrapper that documents `--root` gets one.
2. Add **`dir`** to the `root_kind` case as a consumer root, alongside `consumer-root|project-root`.
3. Belt and braces: `export CONSUMER_ROOT="$root"` next to the existing `OD_*_GLOBS` exports, so any gate reading that variable defaults correctly even if its header says nothing.

~~Until this is fixed, 85 of the 287 verdicts in §9.2 are statements about the wrong directory and must not be read as findings about this repository. The 95/6 split is a true report of what the sweep did; it is not yet a true report of what this tree is.~~

FIXED 2026-09-02, and re-measured by a completed sweep. The strike-through above is kept because the number it carries is what the fix had to move.

The change. `resolve_argv` in `scripts/verify-all-constitution-rules.sh` no longer gates the usage-header lookup behind the gate's own `--root)` case arm. It now asks three questions of the gate, each with a real counter-example in this pin's corpus, and one of the three was NOT in the remedy as written above:

	Question	Why it is not optional
A	Is the <code>--root</code> <kind> text	<code>covenant_propagation_wrappers_generate.sh</code> carries <code>--root <consumer-root></code> inside the here doc template it emits — the interface of

	Question	Why it is not optional
	in the gate's OWN leading comment header?	the wrappers it generates, not its own. A file-wide grep reads generated text as a declaration. Header-scoping changes the answer for exactly 1 file of 286, and it is that one.
B	Will some parser actually RECEIVE it — its own --root) arm, or one in a lib/*.sh it names?	Not in the prescribed remedy, and required. covenant_propagation_suite.sh documents suite gates [--root <consumer-root>] but parses no flags and needs a subcommand first; handing it a root turns a usage refusal into an rc=2 ERROR scored against this tree. Ungating without this test trades one wrong verdict for another.
C	Which root does the generic <dir> mean?	cm_first_refusal_observed.sh declares --root <dir> and means the constitution root (root="\${CONSTITUTION_ROOT:-...}"); cm_oracle_strategy_named_and_independent.sh declares the same <dir> and means the tree under test. The discriminator is the gate's own description on that line, folded across every --root <dir> header line — the first such line is usually the bare SYNOPSIS, which describes nothing.

Plus export CONSUMER_ROOT="\$root" as prescribed — authoritative, not \${CONSUMER_ROOT:-\$root}, so a stale value in the caller's shell cannot redirect 286 gates at another tree.

Root resolution, before and after (--list, counted from its own output):

	project root	constitution root	own default
before	17	3	266
after	104	3	179

87 gates newly receive a root; nothing lost one and no gate's resolved root changed side. 81 are the propagation wrappers; the other 6 are cm_dangerous_combination_fail_closed, cm_killpg_pgid_guard, cm_ledger_row_typed_from_closed_vocabulary, cm_oracle_strategy_named_and_independent,

cm_test_mock_pid_explicit_int and
cm_unchallenged_capability_blocks_release. The last two of those six
were not in the 85: their own default is \${CONSUMER_ROOT:-.}, which
was already the right directory when the sweep is run from the
repository root. They are now explicit rather than accidentally correct.

**All four measured harms are cleared, each re-measured rather
than inferred:**

Harm (as recorded above)	Before	After
81 propagation gates FAIL emitting zero bytes	81 zero-output detail blocks	0
cm_test_mock_pid_explicit_int.sh FALSE FAIL	FAIL rc=1	PASS rc=0
cm_oracle_strategy... output volume	714,162 lines	15,158
two gates at the 900 s timeout	ERROR rc=124 ×2	FAIL rc=1 in 62 s and 65 s — real findings about this tree

The re-run split, and the whole diff between the two runs. Same
command, no flags, nothing silenced:

```
gates run          : 287
PASS               : 187
FAIL   (rc=1)      : 96
ERROR  (rc!=0,1)   : 4
$11.4.32 step 1    : pass
expected-gate ledger: clean
  SWEEP: FAIL — 96 FAIL + 4 ERROR out of 287 gate(s).
```

Against §9.2's **186 / 95 / 6**, exactly **three** rows changed verdict, and they
are the three the fix predicted:

```
cm_dangerous_combination_fail_closed.sh  ERROR rc=124 -> FAIL
rc=1
cm_killpg_pgid_guard.sh                  ERROR rc=124 -> FAIL
rc=1
cm_test_mock_pid_explicit_int.sh          FAIL  rc=1   -> PASS
rc=0
```

Wall clock **867 s** (14 m 27 s) against ≈2 h 45 min, output **3,676,727
bytes / 25,970 lines** against 105,209,937 bytes / 718,345 lines. Evidence
file: <scratch>/sweep-2026-09-02-postC1.txt; the pre-fix run is
preserved beside it. Constitution HEAD at run time 3be10826f3d2 — a

different pin from the f5876a3b700e §9.2 ran against, so **the two splits are not a controlled comparison of this fix alone**; the three-row diff above is, because it is a per-gate join of the two runs.

Still 96 FAIL, and that is the point. Nothing was made green by pointing a gate somewhere convenient. The 81 propagation gates still FAIL at the correct root — they now say so in 76 readable lines each instead of in silence, and what holds them red is the same five third-party carriers §9.4 names.

Proved, not asserted. --prove-failure grew four cases, M16–M19, and its summary count is now DERIVED from the cases that ran (it said “16 mutations” while 18 were running — the §11.4.6 defect this sweep exists to catch elsewhere). It reports **22 mutations, 25/25 green, exit 0**. Each new case reads the gate in BOTH directions — the control shows the right root arriving, the mutation changes what the specimen gate DECLARES and requires the resolved root to follow, so a resolver with any of these answers written down would pass the control and fail the mutation. Four regressed copies of the sweep were built and run to confirm the battery is not inoperative:

Regression applied to a scratch copy	Caught by	Exit
re-gate the header lookup behind the gate's own --root) arm (the original C1a)	M16	1
delete the dir arm from the root_kind case (the original C1b)	M17	1
ungate without the parser-evidence test (test B)	M18	1
remove export CONSUMER_ROOT	M19	1

M17 earned its keep during development rather than after it: the first implementation read only the FIRST header line mentioning --root <dir>, which is the bare synopsis, and M17 failed on the spot.

Honest boundary (§11.4.6). The `<dir> → constitution-root` branch is correct and is proved by M17 on a specimen, but it changes no real gate at this pin: `cm_first_refusal_observed.sh` is the only gate that would take it, and it declares `--selftest`, which `resolve_argv` prefers and returns on first. The branch is a guard against the next gate of that shape, not a change to this run.

FOUND WHILE FIXING, NOT FIXED — the sweep WRITES into the submodule it consumes. `covenant_propagation_wrappers_generate.sh` is discovered as a gate and invoked bare, and bare is its WRITE mode (`--check` is the read-only one its own header documents). Its row in the run above reads `covenant_propagation_wrappers_generate.sh: wrote 162 wrapper file(s)` and it is scored **PASS**. No damage today — the generated bytes are identical to what is already there, and `git -C submodules/constitution status --short` is unchanged after the run — but a read-only verification sweep is mutating a consumed submodule on every invocation, and only idempotence is standing between that and a real edit. This belongs with **C8** (non-gate files invoked as gates) and is left for that item rather than folded into C1.

C2 — README.md has no badge row

- **Gate:** `cm_readme_badge_row_at_top.sh` (§11.4.259), `argv --root <repo>` — correctly resolved, so this is a real finding.
 - **Output:** FAIL — no badge row found at the top of `.../README.md` (first non-blank line after the H1 must be a pure badge row).
 - **File:** `README.md`. Measured: the first non-blank line after `# vasic` is a blockquote (`> **No server-side CI at this umbrella root...**`).
 - **Fix:** author a machine-derived badge row per §11.4.259 (each badge derived from a real source, never hand-typed colours), or record the gap as a tracked §11.4.197 item. Note the existing blockquote is load-bearing content and should move below the badge row, not be deleted.
-

C3 — scripts/audit/zero_findings_sweep.sh does not exist

- **Gate:** `cm_zero_findings_audit_sweep.sh` (§11.4.261), `argv --root <repo>`.
- **Output:**
FAIL ... reason=SWEEP_SCRIPT_MISSING (§11.4.261 mandates a mechanical audit sweep — none declared/found).
- **File:** `scripts/audit/zero_findings_sweep.sh` — **verified absent** at the repository root.

- **Fix:** write the sweep (closed 10-class finding vocabulary, machine-readable ledger), or record the gap. If written it must also be registered in `scripts/check-registry.tsv` or R5 will fail the registry check.
-

C4 — `docs/findings/zero_findings_ratchet.tsv` does not exist

- **Gate:** `cm_zero_findings_monotone_ratchet.sh` (§11.4.261(C)), `argv --root <repo>`.
 - **Output:** FAIL ... reason=RATCHET_SNAPSHOT_MISSING (§11.4.261(C) mandates a checked-in brownfield ceiling -- none found).
 - **File:** `docs/findings/zero_findings_ratchet.tsv` — **verified absent**.
 - **Fix:** snapshot the brownfield ceiling. **This is an operator decision, not an agent one** — §11.4.224(E) / §11.4.66 require the adoption question (immediate hard floor vs one-time ratchet vs phase-in) to be put to the operator before first enforcement. Depends on C3 existing first.
-

C5 — 7,577 test functions carry no oracle-strategy annotation

- **Gate:** `cm_oracle_strategy_named_and_independent.sh` (§11.4.245).
 - **Output at the CORRECT root** (the run's own figure is invalid per C1):

```
CM-ORACLE-STRATEGY-NAMED-AND-INDEPENDENT: FAIL — 7577 test
function(s)
  with no valid closed-set oracle-strategy annotation
 (§11.4.245)
```
 - **Files:** distributed across the owned fleet's test corpora.
 - **Fix, in order:** (i) fix C1 so the number is measured against this tree on every run; (ii) decide the corpus scope — the gate currently walks every owned submodule, and §11.4.35 lets a consumer bind a scoped corpus as DATA; (iii) annotate each test with its closed-set oracle strategy, or adopt a §11.4.135-style monotone-decreasing ratchet. **7,577 is not a one-session fix and should not be presented as one.**
-

C6 — four consumer-side artifacts the §11.4.268-family gates require were never created

Mixed (**b + c**), counted in (c). The upstream half: these gates derive the consumer root as <constitution>/.., which under this repository's submodules/constitution/ layout resolves to <repo>/submodules/ instead of <repo>/ — so their error messages name a path that could never exist. Measured: neither --root nor CONSUMER_ROOT overrides it. **The ours half, and the reason these rows sit in (c): the artifacts are absent at the correct path too**, so fixing the upstream walk alone would flip nothing.

Gate	Missing artifact (checked at BOTH <repo>/ and <repo>/submodules/ — absent at both)	Verdict detail
cm_dependency_register_verdicts.sh	docs/requests/dependency_register.jsonl (§11.4.270)	DRV-A0-SEAM-PRESENT FAIL — the E6 register is absent or unreadable
cm_mechanism_observed_refusing.sh	docs/requests/verification_mechanisms.jsonl	MOR-A0-REGISTRY-PRESENT FAIL + MOR-A4-REAL-REGISTRY-RESOLVES FAIL; A1/A2/A3 all PASS
cm_control_needle_required.sh	scripts/lib/critical_blocker_gate.sh (the §11.4.236 acceptance seam)	CNR-A5-WIRED-AT-SEAM BLIND — the wiring question is UNDECIDED, and undecided is never

Gate	Missing artifact (checked at BOTH <repo>/ and <repo>/submodules/ — absent at both)	Verdict detail
		reported as wired; A0–A4 all PASS (5 PASS / 0 FAIL / 1 BLIND)
cm_instrument_trap_scan.sh	scripts/testing/anti_slop/fixtures/traps	ITS-A0-SCANNER-SIGHTED BLIND — this scanner cannot be shown to see anything, so no corpus result below can be believed

Fix: create the four artifacts (or record each as a tracked §11.4.197 gap). Note the honesty of these gates — three of the four report **BLIND**, not PASS, when they cannot see. That is §11.4.201(7)(b) working correctly and should not be “fixed” by making them quieter.
cm_control_needle_required.sh is 5 PASS / 0 FAIL / 1 BLIND: it is one artifact away from green.

C7 — cm_healthcheck_covers_served_ports.sh has no consumer binding

- **Verdict:** ERROR rc=2 — ERROR — both --compose and --manifest are required (this engine is project-agnostic: it never guesses a consumer's paths, §11.4.28/§11.4.35).
- **File:** scripts/verify-all-constitution-rules.sh — the §11.4.35 consumer-registered block that already binds OD_THEME_GLOBS / OD_TOKEN_GLOBS / OD_VISREG_GLOBS / OD_MANIFEST_GLOBS.

- **Fix:** `bind --compose / --manifest` the same way the `OD_*` inputs are bound. **Honest boundary:** nothing in this repository has been built or run in a container yet (`submodules/containers` is present but unused), so the correct binding today may be an explicit §11.4.3 SKIP-with-reason rather than an invented `compose` file. `rc=2` is `COULD-NOT-DETERMINE` and is **never a pass** — it must not be silenced into one.
-

C8 — the sweep discovers library files and batch runners as if they were gates

- **Rows:** `lib/wiring_sweep_precondition.sh` (ERROR `rc=2`) and `covenant_propagation_suite.sh` (ERROR `rc=2`).
- **File:** `scripts/verify-all-constitution-rules.sh`, the discovery line `find "$GATES_DIR" -type f -name '*.sh'`.
- **What they actually are:**
 - `lib/wiring_sweep_precondition.sh` is a **sourced helper**, not a gate. Bare invocation: `REFUSE: command_field_ABSENT – wiring_sweep_precondition needs <result-tsv> and <current-fingerprint>; got result="" fingerprint=""`. It is behaving correctly; we are calling it wrongly.
 - `covenant_propagation_suite.sh` is a **multi-subcommand batch runner** (suite gates / suite mutations) that prints its usage and exits 2 when invoked bare — exactly the shape `gate_ledger.sh` has, which the sweep already special-cases.
- **Fix:** extend the existing special-case pattern in `resolve_argv` — it already has `--selftest`) and `selfcheck`) branches. Add a `gates`) subcommand branch for the suite, and either give `lib/*.sh` helpers a `--selftest` invocation or exclude non-gate library files from discovery with a stated reason. **Do not simply prune `lib/` blindly** — `lib/pointer_carrier.sh --selftest` is a real 5-fixture golden test the sweep correctly runs and should keep running.

FIXED 2026-09-02, together with C8a below — see that item for the design, the signals chosen and rejected with counts, and the measured before/after. The suite is `EXCLUDED` rather than given a `gates`) branch, and the reason is measurable rather than stylistic: **all 81** gate names in the suite's data pack `covenant_propagation_anchors.tsv` resolve to a `cm_covenant_114_<N>_propagation.sh` wrapper that is `ALREADY` ledgered and run individually (81 pack rows, 81 matched, 0 missing), so a `gates`) branch would run the whole family a second time and report 81 duplicate verdicts. (The suite's own header still says “29 script names”; that is stale upstream prose,

not a count of this pin.) The lib/ warning in the fix above was heeded exactly: 8 of the 15 lib/ files expose --selftest or selfcheck and every one of them is still discovered and still run, lib/pointer_carrier.sh among them.

C8a — the sweep invoked a GENERATOR whose bare mode WRITES into the consumed constitution submodule

- **Row:** covenant_propagation_wrappers_generate.sh, invoked with argv: (gate defaults) — and **bare is its WRITE mode**. Its sweep row read wrote 162 wrapper file(s) and was scored **PASS**.
- **File:** scripts/verify-all-constitution-rules.sh, the same discovery line as C8: find "\$GATES_DIR" -type f -name '*.sh'.
- **Damage measured: none.** The generator is idempotent — a re-run over an unchanged data pack rewrites byte-identical files — and git -C submodules/constitution status --porcelain showed only the pre-existing nested submodules/design-toolkit dirt, never a wrapper. **That is the whole finding.** The only thing standing between a read-only audit and a mutated consumed submodule was IDEMPOTENCE: not a guard, not a read-only mode, not intent. This repository does not commit to the constitution submodule at all, so any write there is outside what it owns.
- **Fix (landed 2026-09-02):** a non-gate classifier above the discovery block in scripts/verify-all-constitution-rules.sh. It reads EVIDENCE out of each file — never a name list, because the gate population moved 57 → 286 on one fast-forward and a list written into the sweep is wrong at the next pin.
 - **RESCUE, evaluated first:** a file parsing --selftest or selfcheck exposes a self-verifying entry point and is never excluded. 18 of 286 files qualify; the rescue is what keeps gate_ledger.sh and 8 lib/ files in.
 - **N1 FIXTURE** — a fixtures/ path component. 6 matched, 6 excluded.
 - **N2 SOURCED** — the file's own Usage shows . <file>/ source <file>. 5 matched, 3 rescued, **2 excluded**.
 - **N3 HELPER** — a lib/ component or lib_ prefix, **and** a sibling names it as a path on a non-comment line, **and** no self-verifying entry point. 7 excluded.
 - **N4 SUBCOMMAND** — the Usage declares a mandatory bare positional. 3 matched, 2 rescued, **1 excluded** (the C8 suite).
 - **N5 WRITES-BARE** — one header line binds (no args)/(default) to a write verb. **1 matched**, and it is the generator. It correctly

spares `cm_instrument_trap_scan.sh`, whose (no args) line is a read-only mode.

- **Signals rejected, with the counts that killed them:** the executable bit (278/286 are +x; all three C8/C8a offenders are among them); a `lib/` path alone (15 files, 8 of them real self-verifying checks — excluding on the path would have been a coverage cut); a `GATE=` self-name assignment (58/286 carry none and many are unambiguous gates, and the generator DOES carry one inside the heredoc it emits, so it classifies the dangerous file as a gate); a Side-effects block mentioning writing (102/286, because every mutation test honestly documents its temp fixture); `chmod +x` in the body (~280/286); a missing `CM-` token (20/286, and it flags a real gate while missing both offenders, which name the token in prose).
- **Direction of error, chosen deliberately:** wrongly excluding a real gate silently reduces coverage — the blind-instrument failure this repository polices. Wrongly including a non-gate produces a visible bad row. So every rule demands positive evidence, a file matching nothing is KEPT, and the excluded set is printed with its reason by the run header and by `--list`.
- **Measured result:** discovery 286 → 270, with 16 excluded and every one named. The expected-gate ledger was re-baselined through the deliberate `--update-ledger` path (286 → 270 rows, 16 removals, 0 additions, pin 3be10826f3d2 unchanged). `--prove-failure` grew from 22 to 25 mutations, still exit 0: **M20** proves the generator is not executed (by a sentinel it writes when it runs, not by reading the sweep's own summary), that it is NAMED as excluded, that a real gate in the SAME run is still discovered AND executed, and that deleting the one declaration line re-admits it and the write happens; **M20b** proves the SUBCOMMAND class from the same file with only its usage line changed; **M20c** proves the excluded set is reported rather than dropped in silence.
- **The new split, measured twice.** `bash scripts/verify-all-constitution-rules.sh` now reports **173 PASS / 96 FAIL / 2 ERROR of 271** (270 discovered gates plus the project-side inheritance test), exit 1, step 1 PASS, ledger clean. The post-C1 baseline it replaces was **187 PASS / 96 FAIL / 4 ERROR of 287**, and the delta reconciles exactly and only against the exclusions: $287 - 271 = 16$, $187 - 173 = 14$, $4 - 2 = 2$, $14 + 2 = 16$, and **FAIL is unchanged at 96**. So the 16 excluded rows were 14 PASSes (the generator's wrote 162 wrapper file(s) among them) and the 2 C8 ERRORS. **No FAIL was removed, and no failing gate was hidden by this change.** The figure was measured twice because the first run overlapped two comment-only edits to the sweep and an in-place edit of a running shell script

is a real hazard; the second, clean run reproduced it byte for byte. `git -C submodules/constitution status --porcelain` shows only the pre-existing `M submodules/design-toolkit` after both full sweeps — no wrapper file was written.

- **The 2 surviving ERRORS are left VISIBLE, not excluded:**
`cm_healthcheck_covers_served_ports.sh` (C7 above, an unbound consumer input) and `lib/instrument_trap_scan.sh`, which is rescued by its own `--selftest` and exits 2. Both are rc-2 could-not-determine and neither is a pass. A `lib/` file that returns a real verdict keeps returning it.
 - **Regression caught by the existing battery:** the new SUBCOMMAND rule excluded M18's own specimen, which had borrowed the suite's `g8_suite.sh gates [--root ...]` header. M18 went red and the specimen was re-cut to isolate the `withhold-until-a-parser-exists` property, which is independent of the subcommand shape. **The proof caught the coverage cut in its own harness before any human did.**
-

9.7 What this run does and does not establish

Establishes. The sweep runs to completion; §11.4.32 step 1 is a measured PASS; the project-side inheritance test passes; the propagation family's owned carrier gap is closed (§9.4); and the tree's own §11.4.259 / §11.4.261 / §11.4.245 / §11.4.268-family obligations are unmet in four concretely-named ways (C2–C6).

Does not establish. 85 of the 101 non-PASS verdicts are about the wrong directory (C1). Until that is fixed, this split measures the sweep's argv resolution as much as it measures this repository. A future run after the C1 fix will produce a different — and for the first time meaningful — 95-equivalent figure, and that run's number must be measured, never extrapolated from this one.

Superseded the same day — C1 is FIXED and the successor run is measured, not extrapolated. The paragraph above stands as written about the §9.2 run and is kept unedited, because “this number is not yet about this tree” is exactly the statement a later reader needs in order to know why a second run exists. The successor figure is **187 PASS / 96 FAIL / 4 ERROR of 287**, exit 1, and the per-gate join of the two runs shows exactly **three** changed verdicts. See the FIXED block at the end of **C1** for the change, the before/after root-resolution counts, all four

cleared harms and the four regression proofs. Both run files are preserved side by side; do not quote either split as a standing fact.

Nothing was suppressed, allowlisted, downgraded or silenced to produce this section. No `2>/dev/null` was used anywhere in the run. No scan was narrowed. No gate was skipped. The exit code is 1 and stays 1.
