

# content-boundary-incident-2026-09-01

## Content boundary incident — 2026-09-01

**Status: HISTORY REWRITTEN AND FORCE-PUSHED TWICE — 2026-09-01 and 2026-09-02. THE INCIDENT IS NOT CLOSED.**

Private material was written into this **public** repository, committed, and pushed. The working tree was redacted, and on 2026-09-01 the history was rewritten and force-pushed under explicit operator authorization — **§8B records that execution with its measurements**. On 2026-09-02 a **second** authorized rewrite removed the third party's **first name**, which §2 had deliberately left standing and which §8B's success turned into the only remaining identifier of that person — **§11 records that one**. What neither did is remove anything from GitHub's servers: **twelve** orphaned commits and every byte of the leak blobs **remain fetchable by SHA** until GitHub runs a server-side garbage collection, which only **GitHub Support** can be asked to do. That request — now **one** request covering both rewrites, First Changed Commit 63ac4df32e5f... → 16cd4ba847de... — and telling the third party are the operator's and are **not done**. Nobody may read §8B, §11, or the green gates at the bottom of this file, as a closure of this incident.

The rule that was broken is stated in [docs/content-boundary.md](#): never quote, paste, excerpt or transcribe content from a private repository into a file tracked by a public one. Naming a private *path* is fine. Copying what is inside it is not.

**This document covers TWO waves.** §1–§8 are the first wave: material sourced from a private meeting-notes PDF in the workshop submodule, including a third party's name. **§9 is the second wave** — the ai\_interviewing and workshop matches that §6 named and deferred. §9 assesses all 232 of them, redacts the

29 that are real disclosures, and states why the other 203 are not. §8’s **remediation plan is unchanged by §9** and remains prepared, unexecuted, and unauthorized. **§10, §11 and §12 are the third, fourth and fifth waves of the same incident.** §13 is **NOT a wave of it at all** — it records a **second, separate instance**: a different person, disclosed by a different route, contained without a history rewrite.

# 1 · What was disclosed

The source is a meeting-notes PDF at workshop/chapters/01/... - Notes by Gemini.PDF, inside the **private** workshop submodule (private=true at the provider). It is a Gemini-generated summary of a private 2026-08-27 screen-recording session between the operator and one other person.

Three classes of material crossed the boundary.

| #  | Class                          | What it is                                                                                                                                                   |
|----|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| D1 | Verbatim prose                 | Sentences copied out of the private PDF and presented as quotations.<br><br>The PDF’s topic headings, reproduced as a complete list. A complete heading list |
| D2 | The section-heading list       | is a table of contents for a private document: it discloses the full agenda of a private conversation even though no sentence of it is quoted.               |
| D3 | A third party’s full real name | The full name of the non-operator participant — referred to throughout this document as <i>the</i>                                                           |

| # | Class | What it is                                                                                                |
|---|-------|-----------------------------------------------------------------------------------------------------------|
|   |       | <i>third party named at docs/workshop-curriculum/RECON.md:138 (pre-redaction) and never written here.</i> |

**D3 is the most serious of the three**, and it is worth being precise about why: the private recording's own filename discloses that person's **first name only**. The public files disclosed **first name plus surname**, together with a date, a subject matter, and the fact that this identifiable person participated in a private business conversation. That is personal data about someone who is not the repository owner and who did not publish it. The operator's own name is not treated as a disclosure here — he owns the repository — but the other participant's is.

**Note on the brief that triggered this work.** It located the name at RECON.md:137. The measured line is **138** (grep -n on the pre-redaction blob). Line 137 is the preceding line of the same sentence. The discrepancy is recorded rather than quietly corrected, because line references in this document are evidence.

## 2 · Where it was — exact locations, pre-redaction

Both files were introduced in a single commit and were **byte-identical in every commit since** (verified: git rev-parse <commit>:<path> returns the same blob for all four).

| File                              | Blob     | Lines                                                    | Class     |
|-----------------------------------|----------|----------------------------------------------------------|-----------|
| docs/workshop-curriculum/RECON.md | 101e019c | 126–130 — six heading strings inside the §1.3 blockquote | <b>D2</b> |
| docs/workshop-curriculum/RECON.md | 101e019c | 138 — the third party's full name                        | <b>D3</b> |
|                                   | 101e019c | 138–145 — three quoted sentences plus                    | <b>D1</b> |

| File                                                             | Blob     | Lines                                                                                                                                     | Class  |
|------------------------------------------------------------------|----------|-------------------------------------------------------------------------------------------------------------------------------------------|--------|
| docs/workshop-curriculum/RECON.md                                |          | a quoted tool phrase                                                                                                                      |        |
| specs/001-workshop-curriculum-platform/research/transcription.md | 7c3513d3 | 780 — the third party's full name                                                                                                         | D3     |
| specs/001-workshop-curriculum-platform/research/transcription.md | 7c3513d3 | 1112–1117 — seven heading strings, and the third party's full name at 1116–1117                                                           | D2, D3 |
| specs/001-workshop-curriculum-platform/research/transcription.md | 7c3513d3 | 1140–1146 — a captured grep run <b>over the private text</b> , disclosing which proper nouns appear at which line of the private document | D1     |

**Not treated as a disclosure, deliberately:** the recording's own filename (...<first name> AI workflows - 2026\_08\_27 09\_57 CEST - Recording.mp4 — written elided here, though it appears unelided in the files listed next) appears at RECON.md:62–65, transcription.md:154 and :1074, quickstart.md:83 and :284, and spec.md:17. It carries a **first name only**, it is the artifact's actual name, and the documents are not actionable without it. It is the pre-existing baseline, not new exposure. If the operator decides even that is too much, renaming the artifact in the private submodule is the fix, and it is his call, not an agent's.

### 3 · Which commits carry it — the residual exposure

This is the part redaction does not touch.

| Commit                                   | Date                      | Role                                                                     |
|------------------------------------------|---------------------------|--------------------------------------------------------------------------|
| 63ac4df32e5fd40806a50cd38fde8cdc39587c2c | 2026-09-01 06:47:32 +0200 | <b>introduced both files,</b> with the disclosed content already in them |
| d0b3c64 · 96b2988 · ee3933d              | 2026-09-01                | carry the same two blobs, unchanged                                      |

ee3933d is the current HEAD **and** origin/main **and** github/main. All three configured remotes (origin, github, upstream) point at `git@github.com:milos85vasic/vasic.git`, whose provider visibility is **private=false, visibility=public**. No tag contains 63ac4df.

So, plainly:

1. **The content is public right now**, in four commits, in a repository anyone can clone.
2. It has been public since **2026-09-01 06:47 CEST**.
3. It may already have been **cloned, forked, mirrored, cached by the provider, scraped, or indexed by a search engine or a training crawler**. Whether any of that happened is **UNVERIFIED** and, for most of those channels, unverifiable from here.
4. **Redacting the working tree does not remove any of it**. After this change lands, the disclosed text is still reachable at `git show 63ac4df:docs/workshop-curriculum/RECON.md` by anyone with a clone.

A green `verify-content-boundary.sh` after this change means “*the tip of the tree is clean*”. It says nothing whatsoever about history. Do not report it as if it did.

## 4 · How it happened, and what actually failed

Not carelessness — **diligence pointed the wrong way**. `docs/content-boundary.md` already names this exact failure mode: “*An agent told to document the work comprehensively reaches for an illustrative quote, and the quote is the leak.*” Both documents are anti-bluff

reconnaissance records whose whole purpose is to prove claims with evidence. Quoting the source is the reflex that discipline trains. The authoring agent had no instrument telling it that the source was on the other side of a visibility boundary.

Three distinct failures, only one of which is now closed:

- **F1 — no boundary rule existed when the content was written.**  
docs/content-boundary.md and scripts/verify-content-boundary.sh are **untracked, created later the same day**, after the leak was already pushed. The gate is a *response* to this incident, not a control that failed to fire. **Closed** once those two files are committed and registered.
- **F2 — the gate does not catch class D2, and did not catch this instance of it.** Its match window is **eight normalised words**. Five of the seven heading strings are five or six words long, so they cannot produce an eight-word shingle and are structurally invisible to it. Re-running the same comparison at a **six**-word window found the heading list in **both** files, including the reproduction at transcription.md:1112–1114, which the eight-word gate reported as clean. **Open.**
- **F3 — the gate cannot detect a bare personal name (class D3) at all.** A first-plus-last name is two words. No shingle length that would catch it is usable without drowning the gate in false positives. Name-class disclosure needs a different mechanism — an explicit deny-list of names, held privately — or it needs a human. **Open.**

**The honest reading of F2 and F3: this leak was found by a human-directed audit, not by the gate. The gate found class D1 only.**

## 5 · What was changed (containment)

Working tree only. **Nothing was committed, pushed, tagged, or rewritten.**

### docs/workshop-curriculum/RECON.md — §1.3

- The six heading strings are gone. Replaced by “*a Quick notes section of thematic bullets grouped under **six topic headings***” plus an explicit statement that the strings are private and are not reproduced.
- The three quoted sentences and the quoted tool phrase are gone. Replaced by a **paraphrase written to be a paraphrase** — the same

findings (who proposed the curriculum, what end state is intended, that hosting the material is an assigned action, that the §3 tooling is already in the operator's working set) carried in different words. This was verified, not assumed: see §7.

- The third party's name is gone. Replaced by *“a third party whose full name is private content and is deliberately not written into this repository.”*
- A **Content boundary** callout was added at the end of §1.3, naming the private source **by path only** and linking here.

## **specs/001-workshop-curriculum-platform/research/transcription.md**

- **:780** — the sentence asserting the two names now says both speakers are named in the notes PDF, that this is what makes human attribution cheap, and that the third party's name is deliberately not written into this public repository. The *argument* (human attribution beats diarization here, because the names are already known) survives intact; only the names are withheld.
- **:1112–1117** — the seven heading strings and both names are gone. Replaced by *“a structured summary organised under **seven topic headings**... The headings span the session's technical ground and its business ground”*, with the strings explicitly withheld. The use the section makes of them — that they are a candidate section outline for FR-011 — is unaffected, because that use needs the **count and the shape**, not the text.
- **:1140–1146** — the captured grep output over the private text is gone. The command is retained as a **recipe to run against the private source**, with its output explicitly not reproduced. The argument it supported (the PDF contains transcription-class errors, so the recording must be authoritative) is preserved by describing the two mis-renderings functionally — a one-letter error in the planning toolchain's name, and `llama.cpp` split and capitalised as two English words — without pasting the erroneous strings or their private line offsets.
- A **Content boundary** callout was added at the end of §8, including the forward-looking rule that the transcript, once it exists, is private too: the §5 WER procedure must publish **scores**, never the sampled passages, the human reference, or the machine hypothesis.

**Deliberately left in place:** the proper-noun gazetteer list at `transcription.md:1126–1127` (*MCP, Codegraph, Lumen, llama.cpp, Helix QA, Opus, Fable, RAG*). This is a judgement call and is recorded as one.

These are product and technology names, every one of them already documented publicly elsewhere in this tree — Lumen has its own subsection in RECON.md §3.1, and several have `_content/products/` pages. A vocabulary list of public product names is not a reproduction of private prose, and the gazetteer is load-bearing for FR-038. If the operator disagrees, deleting the list costs the document little.

## 6 · What the sweep found that the brief did not name

The brief supplied line numbers from one earlier pass. An independent sweep — comparing every **six**-word normalised shingle of the private PDF against a **token stream** of every tracked umbrella file, so that text wrapped across source lines is still matched — found three things the brief did not:

1. **transcription.md:1112–1114 reproduces the heading list.** The brief flagged `:1113–1116` for this, which is right, but the eight-word gate scores those lines **clean**, so anyone re-deriving from the gate alone would have concluded there was nothing there. This is F2 above, demonstrated.
2. **RECON.md:143–144 quotes a tool phrase verbatim** — a six-word run naming two of the operator’s indexing tools, lifted straight from the PDF. Outside the `:138–142` range the brief gave. Redacted.
3. **The name survives locally in `.ashlrcode/genome/knowledge/discoveries-auto.md`**, which caches agent tool output and holds a substantial verbatim excerpt of the PDF. It is **git-ignored** (`.gitignore:82`) and **untracked** — confirmed against `git ls-files` — so it was never published and is **not part of the public exposure**. It is flagged because it is a live local copy of private content in a directory that is *mostly* tracked, and one `.gitignore` edit away from becoming a second incident. **No action taken** — it is a generated cache owned by another tool.

The wider sweep also confirms this incident is **not the only content-boundary finding in the tree**, and the rest is **out of scope for this work and remains unremediated**. Of the 377 baseline matches, 37 come from the workshop submodule (29 from the PDF, 8 from that submodule’s governance carriers appearing in `quickstart.md:315,317`). The other **340 come from `design-toolkit/` and `ai_interviewing/`** — both private — landing in `_analysis/`, `_content/products/`, `docs/constitution-adoption/INVENTORY.md`, and, notably, `RECON.md:408/:460/:462/:489`, which quote private `ai_interviewing`

source code and scripts verbatim. **Those are a separate incident that has not been assessed, decided, or fixed.** They are a different risk class — the operator's own code and prose rather than a third party's personal data — but they are on the same public remote.

## 7 • Verification of the redaction

The paraphrases were checked rather than trusted, because a paraphrase written by the same process that wrote the quote tends to stay too close to it.

Method: normalise the private PDF and each redacted file to lowercase alphanumeric token streams; build every **six**-word shingle of the PDF; slide the same window over each file's token stream (crossing line boundaries, so wrapped text cannot hide).

- **Before:** 23 locations, 97 shingles across tracked umbrella files.
- **After: 9 locations, 54 shingles — every one of them the artifact's own filename and timestamp** (...2026 08 27 09 57 cest...), the accepted baseline described in §2. **Zero prose overlap remains.**
- A `grep -rn` for the third party's surname over the tracked umbrella tree returns **no tracked file**. The only surviving hits are in the git-ignored cache described in §6.3. (The search term is deliberately not written here — reconstruct it from the pre-redaction blob, `git show 63ac4df:docs/workshop-curriculum/RECON.md | sed -n '138p'`, and do not paste the result into this repository.)

Gate results are recorded at the end of this document.

## 8 • Full remediation — PREPARED, NOT EXECUTED, NOT AUTHORIZED

**Nothing in this section has been done. Nothing in it may be done by an agent.**

A history rewrite plus a force-push is a destructive operation. Constitution §11.4.113 requires **explicit per-session operator authorization** before any force-push, and the project carriers additionally require a green §9.1.5 post-op gate. **The operator has not given that authorization.** This is his decision — it has costs that only he can weigh — and the plan below exists so that the decision can be made on facts rather than re-derived under pressure.

## 8.0 · Decide first: is a rewrite even worth it?

Answer this before anything else, because **a rewrite is not a clean undo** (see §8.4), and the honest answer is sometimes *no*.

It is **worth it** if the third party's identity being publicly linked to this private session is itself the harm, and reducing the number of people who can casually find it has value.

It is **not worth it** if the content is already mirrored or indexed, in which case the rewrite costs every collaborator a re-clone and buys close to nothing — and **a targeted conversation with the third party may be worth more than any git operation.**

The third party is the person with the most at stake and the least say. **Telling them is a defensible first step regardless of what is decided about git**, and it is the operator's call to make, not an agent's. This document takes no outward-facing action of any kind.

## 8.1 · Before touching anything

1. **Hardlinked backup of the full repository, including .git** (Constitution §9). A history rewrite is exactly the destructive class that rule exists for.
2. Record `git rev-parse HEAD` and the current `origin/main`.
3. **Confirm every other active agent and worktree in this tree has stopped.** A rewrite under a concurrent writer loses work. At the time of writing, several agents were active here.
4. `git fetch --all` and confirm no unmerged remote work would be discarded.

## 8.2 · The rewrite

Rewrite `63ac4df..HEAD` (four commits), replacing the two blobs with their redacted content while preserving every other change.

- `git filter-repo --replace-text <rules>` is the appropriate tool — it is the maintained replacement for `filter-branch`, and its `--replace-text` mode substitutes the disclosed strings without needing the files to be reconstructed by hand.
- **The rules file itself contains the disclosed strings.** It must be written **outside the repository**, never committed, and shredded afterwards.
- `filter-repo` removes the `origin` remote by design; it must be re-added deliberately.

- Every commit from 63ac4df onward gets a **new SHA**. Every existing clone, every open branch, and every reference to those SHAs — including any in CONTINUATION.md or in these governance documents — is invalidated and must be updated. **This document's own §2 and §3 SHAs become historical references to a discarded history**, which is the correct outcome, and the document should say so at that point rather than being edited to hide it.

### 8.3 · The push

`git push --force-with-lease` — never bare `--force`. `--force-with-lease` refuses if the remote moved since the last fetch; bare `--force` silently destroys whatever it finds.

**This step requires the explicit per-session authorization named above.** Both site submodules deploy from pushes; `milosvasic.ru` self-publishes via an active workflow that **must not break** (a documented deviation held for production uptime). Confirm the umbrella rewrite cannot disturb either before pushing.

### 8.4 · Why the rewrite is still not a complete remedy — state this to the operator plainly

- **GitHub retains force-push-orphaned commits and serves them by SHA** until they are garbage-collected, and the timing of that GC is not under the repository owner's control. Anyone who recorded 63ac4df — from a notification email, a webhook payload, an Actions log, a PR page, a mirror, or this document — **can still fetch the old content by SHA after a successful force-push**. A rewrite alone therefore does **not** end the exposure.
- Ending it requires **asking GitHub Support to purge the orphaned objects and caches**, and they are the only party who can. **That is an outward-facing action and is out of scope for this work — it is the operator's to initiate, deliberately, not an agent's**. It is listed here because a plan that stops at the force-push would be a plan that quietly overstates what it achieves.
- **Forks, mirrors and existing clones are unreachable by any of this.**
- **Search-engine and archive caches** persist independently and have their own removal processes.
- **Rotation.** No credential, key or token was disclosed — the material is prose and a personal name — so there is nothing to rotate in the secrets sense. **Personal data cannot be rotated at all**, which is

precisely why D3 is the serious class and why §8.0 puts the conversation with the third party ahead of the git operation. Before concluding this, re-run a secret scan over the affected blobs rather than taking this paragraph's word for it.

## 8.5 · Prevent recurrence

- **Commit and register scripts/verify-content-boundary.sh.** It is untracked. R5 in verify-check-registry.sh will fail until it is entered in scripts/check-registry.tsv, and that failure is the registry working correctly.
  - **Wire it into scripts/pre-push-gates.sh.** A boundary check that only runs when someone remembers to run it did not prevent this incident and will not prevent the next one.
  - **Close F2:** lower the match window, or add a heading-list-specific check that compares private headings against public files at their natural length. Pair it with a mutation proof that seeds a five-word heading and requires a catch (Constitution §1.1).
  - **Close F3:** a privately-held name deny-list, read from outside the tracked tree, so the gate can catch a bare personal name without the list itself becoming a disclosure.
  - **Assess the 340 out-of-scope matches** in §6 as a separate piece of work with its own decision record.
- 

## 8A · The remediation, REHEARSED ON A CLONE — NOT EXECUTED, REQUIRES OPERATOR AUTHORIZATION

**Status: REHEARSED ON A CLONE, NOT EXECUTED — REQUIRES OPERATOR AUTHORIZATION.** Nothing in this section was done to <ext-volume-host>/Projects/vasic. No git push, no --force, no filter-repo, no fetch touched the real repository. Constitution §11.4.113 still requires explicit per-session operator authorization for the force-push, and it has still not been given. §8 above is **unchanged**; this section sits beside it and records where running the plan corrected it.

**What this section is for.** §8 was a plan that had never been executed even once, so nobody knew whether it worked. On **2026-09-01** the whole of it was run end to end on a full clone in a scratchpad, and

every claim below is a measurement taken from that run rather than an expectation. Where the rehearsal contradicts §8, §8A.9 says so explicitly rather than editing §8 to look right in hindsight.

**Isolation.** All work happened in `.../scratchpad/rehearsal/` on `tmpfs`. The real repository was touched only by `git clone`'s `upload-pack` (read-only), `git cat-file` and `git ls-tree`. Every destructive command was preceded by a case `"$PWD" in .../rehearsal/run*) ... ;; *) exit 1 ;;` esac guard whose output is quoted in the run log. Eight agents were writing to the real tree throughout; the clone isolated the rehearsal from them completely, and §8A.9 records what that concurrency proved about the plan.

### 8A.1 · The exposure, re-measured on the clone

The clone reproduces the leak exactly. §2 and §3 name **two** files; the measurement finds **four**, because waves 2 and 3 added two more and §8 was never updated to match.

| Path                                                             | Blob                                     | Blob bytes | In commits               | D li |

| Path | Blob | Blob bytes | In commits | D li |
|------|------|------------|------------|------|
|      |      |            | 4 commits  |      |

Each blob is byte-identical in every commit that carries it — a single blob per path, not one per commit. The four commits are 63ac4df → d0b3c64 → 96b2988 → ee3933d, all 2026-09-01, all authored Милош Васић.

Two further facts, both measured rather than assumed:

- **No other object in history carries any of it.** An exhaustive scan of every object in the clone — `git cat-file --batch-all-objects`, which sees reachable, unreachable, packed and reflog-held objects alike; **7,505 objects, 6,231 text blobs** — found each of the 51 usable disclosed-line literals in **exactly one blob**, and that blob is always one of the four above. Nothing else in 103 commits copies the material.
- **No tag and no other branch contains it.** 63ac4df is an ancestor of `refs/heads/main` only. All four tags (`pre-restyle`, `v1.7.1`, `v1.7.2`, `v1.8.0`) predate it. `git ls-remote` against the public remote returns **`refs/heads/main` and those four tags and nothing else**, so the force-push would touch exactly **one** remote ref — which is also precisely what `filter-repo` wrote into `.git/filter-repo/changed-refs: refs/heads/main`.

## 8A.2 • Tooling — `git filter-repo` is present

`git-filter-repo` resolves on PATH at `<home>/local/bin/git-filter-repo`, backed by the importable module `git_filter_repo` at `<home>/local/lib/python3/site-packages/git_filter_repo.py`, against `git 2.50.1`. **No fallback was needed:** neither `git filter-branch` nor BFG was used, and neither should be. `filter-branch` is deprecated and would have been dramatically slower on a 3.96 GiB pack, and BFG is not installed on this host.

## 8A.3 · The procedure that was actually run, with the verification after each step

Every command below was executed, in this order, with the measured wall-clock beside it. \$SCRATCH is the scratchpad rehearsal directory; \$W is \$SCRATCH/work, held **outside** the repository. Substitute nothing by hand — the SHAs here are this run's, and a real run must read its own out of .git/filter-repo/.

**Step 0 — hardlinked backup and a recorded starting point (§8.1, unchanged and correct).** Not re-measured here because the rehearsal's clone is the backup; in a real run this is Constitution §9 and is not optional.

```
git rev-parse HEAD #
ee3933d46211d6001ffc23acab480e0cffdc99c6
git ls-remote git@github.com:milos85vasic/vasic.git
# read-only; no fetch, no object transfer
```

*Verify:* the remote's refs/heads/main equals local HEAD. It did.

**Step 1 — full clone, all refs, all tags.** --no-local forces the git-aware transport, so the clone is a self-contained copy with no hardlinks into and no alternates pointing at the real object store. That property is what makes the rest of this safe.

```
git clone --no-local --no-single-branch \
file://<ext-volume-host>/Projects/vasic "$SCRATCH/vasic-clone"
```

**Measured: 557.04 s (9 m 17 s), peak RSS 2.26 GB, 4.6 GB on disk, 3.96 GiB pack.** *Verify:* HEAD = ee3933d...; 103 commits; 7,505 reachable objects; all four leak blobs resolve with their documented byte sizes; a single pack, no loose objects.

**Step 2 — pin the redacted replacement content, outside the repository.** For RECON.md and transcription.md the working-tree files are redaction-only and were pinned as-is. For quickstart.md and llm-bridging.md the working tree also carried **unrelated concurrent edits from other agents**, so the pinned versions were built as *pre-image plus only the disclosure hunk*. Each pinned file is fixed by sha256, and the rewrite aborts if a byte moves:

| Pinned file  | sha256                                                           |   |
|--------------|------------------------------------------------------------------|---|
| RECON.pinned | 663fbba60ed81a134d653eaeaa9bd35c06a2464afb5fa4b5f904c9ccc8403d8c | ( |
| TRANS.pinned | a4e2ddf05f42b277e1d13f6406e52fd3509e02476d581e48ca571c1ecd7a1870 | 6 |
| QUICK.pinned | 91d33086273443a796558987733f7f5c5812fba0c123fdb48c3a356aa7395f91 | 1 |
| LLMB.pinned  | b1371f1f77810930aad21637deb94bb0b272a92e6acacc8cbc1424eef407c52c | 2 |

*Verify:* diff each pinned file against its pre-image and confirm the hunk count and the 57 removed lines / 4,400 bytes in §8A.1. It matched.

**Step 3 — the rewrite.** Keyed on `blob.original_id`, so the four blobs are replaced wholesale and **no copy of the disclosed strings exists anywhere in the procedure:**

```
cd "$SCRATCH/runB"
case "$PWD" in */scratchpad/rehearsal/runB) : ;; *) echo ABORT;
    exit 1 ;; esac
export FR_PINNED_DIR="$W"
git filter-repo --blob-callback "$(cat "$W/blob-callback.py")"
```

The callback is 30 lines: a {blob-sha → pinned-filename} map, a sha256 assertion per pinned file, and `blob.data = ...`. **Measured: 391.23 s (6 m 31 s), peak RSS 6.04 GB.** *Verify:* see §8A.4 — all of it.

**Step 4 — the push, rehearsed against a local stand-in remote.** A hardlinked bare clone of the *pristine* history stands in for GitHub, so the lease semantics are exercised for real without any network:

```
git clone --bare "$SCRATCH/vasic-clone" "$SCRATCH/fake-
    remote.git" # 0.02 s, hardlinked
# NEGATIVE CONTROL (§1.1 paired mutation) – a wrong lease MUST be
    refused:
git push --force-with-lease=refs/heads/main:0000...0000 fakeorigin
    main
# ! [rejected] main -> main (stale info)      remote unchanged
    at ee3933d
# POSITIVE – the correct lease:
git push --force-with-lease=refs/heads/
    main:ee3933d46211d6001ffc23acab480e0cffdc99c6 \
```

```
fakeorigin main
# + ee3933d...b0ab4b4 main -> main (forced update)
```

**Measured: 12.29 s.** Using the explicit =<ref>:<expected-sha> form is deliberate — it means the lease never has to be established by a git fetch, and §8A.9 records why that matters. *Verify*: the negative control was refused and left the remote at ee3933d; the positive updated it to the rewritten tip. Both held.

**Total measured wall-clock for the whole procedure:  $\approx$  17 m 50 s** (clone 557 s + snapshot 9 s + rewrite 391 s + residue scan 7 s + fsck 94 s + push 12 s), peak RSS 6.04 GB — about **10 % of this host's 62 GB**, comfortably inside the §12.6 60 % cap.

## 8A.4 · What the rewrite was verified to have done — exhaustively

Every check below was run against the rewritten clone after the rewrite.

**Residue — nothing of the material survives anywhere.**

- **51 of 51 disclosed-line literals: 0 matches, in 0 blobs**, across all 7,505 objects (--batch-all-objects covers unreachable and reflog-held objects too, not just what the refs reach). Before the rewrite all 51 matched.
- **Name class: 0.** Four distinctive capitalised tokens were derived mechanically as *present in the removed lines and absent from every redacted file*, then confirmed to occur in  $\leq 4$  blobs in pristine history. After the rewrite all four are gone from every blob that carried them as part of the disclosure. One single occurrence of one token survives, in \_analysis/top20/caf-bridle.readme.txt — a vendored third-party README added in commit dd2d684, long before this incident, where the word is an ordinary lexical coincidence. It is **not** disclosure and it is correct that the rewrite left it alone.
- **The old objects are unresolvable locally.** git cat-file -t on 63ac4df, ee3933d, 101e019c, 7c3513d3, a4aed8a4 and 7801a537 all return “could not get object info”. git reflog --all is empty and git fsck --unreachable reports **0** unreachable objects — filter-repo expires the reflog and prunes as part of its own run.
- git fsck clean in **93.95 s**. 7,505 objects, 3.96 GiB pack — unchanged, as expected: the four replaced blobs are of near-identical size.

**Collateral damage — none.** The full tree at HEAD was captured before and after and compared entry by entry (`ls-tree -r -t --full-tree`, **6,246 entries**):

- Path set **identical** — 0 paths added, 0 removed.
- **9 entries changed, and only 9:** the **4 target blobs**, and the **5 tree objects** that are exactly their ancestor directories (`docs`, `docs/workshop-curriculum`, `specs`, `specs/001-workshop-curriculum-platform`, `specs/001-workshop-curriculum-platform/research`).
- **6,237 of 6,246 entries are byte-identical**, same mode, same type, same object SHA.
- Each rewritten blob is **byte-identical to its pinned file** — verified with `cmp`, all four.
- `git status` in the rewritten clone is **clean**: the rewrite lands the redaction in history *and* in the checkout in one operation.

**Identity — 103 commits, 4 SHAs changed, everything else preserved.**

| Old      | New (this rehearsal) | Subject                                             |
|----------|----------------------|-----------------------------------------------------|
| 63ac4df3 | fc7574b2             | SpecKit 001 through plan phase...                   |
| d0b3c649 | 7b4df26d             | SpecKit 001 through tasks...                        |
| 96b2988e | 4ee9e8de             | gates: distinguish ‘could not run’ from ‘failed’... |
| ee3933d4 | b0ab4b44             | gates: defer live-production specs...               |

- **98 of 103 commit SHAs are unchanged.** Only 63ac4df and its three descendants move, because they are the only commits at or after the earliest rewritten one.
- **Author name, author email, author date, committer name, committer email, committer date and subject are byte-identical for all 103 commits** — compared as a sorted stream with SHA, tree and parent stripped. `filter-repo` preserves the whole identity envelope; only the SHA moves, and it moves because the tree it commits to has changed. That is the definition of a content hash working correctly.
- **All four tags unchanged**, all still pointing at their original objects — they predate 63ac4df.

- `.git/filter-repo/first-changed-commits` contains exactly one line, the old→new mapping for 63ac4df. That file is what GitHub Support asks for (§8A.7).

## 8A.5 · What the rewrite changes about identity, stated plainly

Every commit at or after the earliest rewritten one gets a new SHA. Here that is **4 of 103**, because 63ac4df is the fourth commit from the tip — the blast radius is small, but it is not zero, and it is exactly the disruption that makes this a decision rather than a chore:

- Anyone holding a clone has a history that no longer shares a tip with the remote. Their next `git pull` will not fast-forward. They must **rebase, not merge** — GitHub’s own guidance — because merging their old branch back would reintroduce the deleted content.
- Any recorded reference to 63ac4df, d0b3c64, 96b2988 or ee3933d — in a notification email, a webhook payload, an Actions log, a bookmark, or **in this document’s own §2, §3 and §9.6** — becomes a reference to a discarded history. §8.2 already predicted this and said the document should say so rather than be edited to hide it. It is said here.
- **Three tracked files quote 63ac4df in prose** and would become dangling evidence references: `helix-deps.yaml` (2 places), `scripts/verify-governance-cascade.sh` (1) and `scripts/verify-manifest-pins.sh` (2). `filter-repo` rewrites old hashes in **commit messages**, not inside blob content, so these survive the rewrite untouched and stale. None is functional — all five are anti-bluff evidence citations — but under §11.4.6 a citation that no longer resolves is a defect and would need a follow-up commit. **§8 does not mention this.**

## 8A.6 · The consequences, measured rather than assumed

**Gitlinks and `helix-deps.yaml` survive intact — verified, not assumed.**

- HEAD carries **9 gitlinks** (`ai_interviewing`, `design-toolkit`, `milosvasic.ru`, `monetization`, `submodules/constitution`, `submodules/containers`, `submodules/superspec`, `vasic.digital`, `workshop`). After the rewrite all **9 are byte-identical**, and the before/after tree comparison reports `gitlinks=0` changed. Across all 103 commits there are **93 distinct (path, sha) gitlink pairs** over those same 9 paths, and the rewrite touched none of them.

- `helix-deps.yaml` contains **13 ref: mentions**, of which **8 are actual `deps[].ref` pins** holding **9 distinct 40-hex SHAs**. Every one of them names a commit in a  *submodule*  repository: the intersection of those SHAs with the umbrella’s own 103 commits is **empty**. The blob SHA of `helix-deps.yaml` at HEAD is unchanged by the rewrite, and so is `.gitmodules`.
- **Why they survive.** Gitlinks point *outward*. A gitlink is a commit entry in the umbrella’s tree whose SHA belongs to another repository’s object graph, which this rewrite never enters. The intuition was right; it is now measured. **Cascade check C9 and `scripts/verify-manifest-pins.sh` would still pass unchanged after the rewrite.**

**Who actually has the old objects — measured from the provider, read-only.**

| Fact                                   | Measured 2026-09-01                                           |
|----------------------------------------|---------------------------------------------------------------|
| Visibility                             | <code>private=false,</code><br><code>visibility=public</code> |
| <b>Forks</b>                           | <b>0</b> ( <code>forks_count 0, network_count 0</code> )      |
| Watchers / stars                       | 0 / 0                                                         |
| <b>Pull requests, any state</b>        | <b>0</b>                                                      |
| Branch protection on <code>main</code> | none — a force-push would not be blocked                      |
| Repository page views, 14 d            | <b>0</b> ( <code>count 0, uniques 0</code> )                  |
| Popular paths / referrers, 14 d        | <b>empty</b>                                                  |
| Clones, 14 d                           | 62 / 26 unique — <b>but the window ends 2026-08-31</b>        |

Read those carefully, because they cut both ways.

- **The good news is real.** Zero forks means no fork on the provider retains the objects. Zero pull requests means the whole “cached views and references in pull requests” problem — the main thing GitHub Support exists to fix here — **does not apply to this repository**. Zero page views means nobody browsed the file on `github.com`.
- **The honest gap.** GitHub’s traffic API covers **2026-08-18 ... 2026-08-31**, and the leak landed **2026-09-01 06:47 CEST**. There is therefore **no clone data yet for the exposure window at all**, and whether anyone cloned during it is **UNVERIFIED**. Re-run `gh api repos/milos85vasic/vasic/traffic/clones` on 2026-09-02 or later;

that is the single cheapest piece of evidence available for the §8.0 decision, and it does not exist yet.

- Anonymous clones are invisible to the provider regardless, and search-engine and archive caches persist independently with their own removal processes. Neither is measurable from here.

**A force-push does not delete anything on the server — demonstrated, not quoted.** On the stand-in remote, immediately after a successful `--force-with-lease`:

```
63ac4df3 -> commit      # still resolves
101e019c -> blob        # still resolves, all 98,599 bytes
readable by SHA
reachable from any ref? 0 # orphaned – but orphaned is not
deleted
```

Only after `git reflog expire --expire=now --all && git gc --prune=now` (11.86 s) did both become unresolvable. **That is precisely the GitHub situation**, and it is why §8.4 is right that the rewrite alone is not a remedy: the content stays fetchable by SHA to anyone who recorded it, until a server-side garbage collection runs, and the timing of that is not the repository owner's to control. What removes it is a **support request** — §8A.7.

**One incidental finding, checked because it would have been far worse than the incident.** History contains a **1,784 MB blob** at `workshop-git-backup-2026-08-29/objects/pack/pack-053fbf69...pack` — a committed copy of the **entire object store of the private workshop submodule** — on commit `a8137db` (“Auto-commit”, 2026-08-29). **It is not public.** `a8137db` is not an ancestor of `main`, the path does not exist at `HEAD`, and `git ls-remote` confirms the public remote carries only `refs/heads/main` and four tags: the branch `backup/pre-untrack-git-backup-a8137db` exists **locally only and was never pushed**. No action is required, and one prohibition follows: **that branch must never be pushed**. It is recorded here because a local-only hazard that nothing checks is one accidental `git push --all` away from being a much larger incident than this one.

## **8A.7 · The GitHub Support request — text prepared, DO NOT SEND**

**This is an outward-facing action and it is the operator's alone.** Nothing was sent, no issue was opened, no support portal was contacted. GitHub's own instructions ([Removing sensitive data from a repository](#)) require the request to name the repository, the number of

affected pull requests, and “*the First Changed Commit(s) reported by git-filter-repo*”. Send it **only after** the force-push has succeeded — the first-changed-commit mapping does not exist until then.

Two things to fix in the text before sending: replace <NEW-SHA> with the value from the real run’s .git/filter-repo/first-changed-commits (**not** this rehearsal’s — the pinned content will differ, so the SHA will differ), and re-check the pull-request count if any PR has been opened since 2026-09-01.

**Subject:** Request to purge orphaned commits and cached views after a history rewrite — milos85vasic/vasic

Repository: milos85vasic/vasic (public, owned by me).

I have rewritten this repository’s history to remove personal data about a **third party** — a named individual who is not me, who did not publish the material, and who has no control over it — together with verbatim prose quoted from a private document. The material was committed on 2026-09-01 at 06:47 CEST and force-pushed out on .

I have already completed the following:

- Rewrote the affected commits with `git filter-repo` and force-pushed the cleaned history to `refs/heads/main` using `--force-with-lease`.
- Confirmed the sensitive content is absent from every object in the rewritten history.
- Confirmed there are **no forks** of this repository (`forks_count 0, network_count 0`).
- Confirmed there are **no pull requests** in this repository, in any state — so the count of affected pull requests is **0**.
- Confirmed no Git LFS objects are involved; the repository declares no LFS filters.
- Confirmed no other branch or tag contains the affected commits; only `refs/heads/main` was rewritten.

**First Changed Commit, as reported by `git filter-repo`:**

- old: 63ac4df32e5fd40806a50cd38fde8cdc39587c2c
- new: <NEW-SHA>

The following commits were orphaned by the force-push and, at the time of writing, still resolve by SHA at <https://github.com/milos85vasic/vasic/commit/<sha>>:

- 63ac4df32e5fd40806a50cd38fde8cdc39587c2c
- d0b3c6493a7f635a0a71d81f049069fb2741ea9c
- 96b2988ef61f4adee1bba51ee1c42efcb5f4408e
- ee3933d46211d6001ffc23acab480e0cffdc99c6

Please run a garbage collection on the server to expunge these orphaned objects from storage, and remove any cached views that still serve them.

On your criterion that support removal is for cases where “*the risk can’t be mitigated by rotating affected credentials*”: **no credential is involved and none can be rotated**. The disclosed material is another person’s full name, linked to a dated private business conversation, plus prose quoted from a private document. Personal data cannot be rotated, reissued or revoked. Rotation is not an available mitigation here, which is precisely why I am asking for the purge.

Thank you.

## 8A.8 · Prerequisites the rehearsal showed are load-bearing

- **Commit the working-tree redaction, or fold it into the rewrite — but decide which.** The redactions of §5, §9.3 and §9.4 are still **uncommitted working-tree modifications**. The procedure in §8A.3 folds them into history directly, which leaves a clean git status and no second commit. If instead §8’s --replace-text route is taken, history gets marker lines and the working-tree redaction still has to be committed afterwards, as a separate step, with a confusing diff. §8 does not sequence this at all.
- **Stop the other agents first, and mean it.** §8.1 item 3 says this. The rehearsal found the hard evidence for why: between 14:00 and 17:18 on 2026-09-01, concurrent agents modified quickstart.md and llm-bridging.md for reasons unrelated to any redaction. Had those files been substituted wholesale from the live working tree, the rewrite would have injected unrelated in-flight work into four commits from earlier that morning.
- **Do not git fetch between the rewrite and the push.** Fetching from the un-rewritten remote pulls the leaked objects straight back into the cleaned clone. This is why §8A.3 step 4 uses the explicit --

force-with-lease=<ref>:<sha> form, which needs no remote-tracking ref and therefore no fetch. §8.1 item 4 recommends `git fetch --all` *before* the rewrite, which is fine and correct; the hazard is a fetch *after* it.

- **filter-repo removes origin** — §8 says so and it is confirmed. It also **converts remote-tracking refs into local branches**: `refs/remotes/origin/backup/pre-untrack-...` came back as `refs/heads/backup/pre-untrack-...`. Given the 1.78 GB private packfile on that branch (§8A.6), the state after a real rewrite is one where a private-object-bearing branch is a *local branch* rather than a remote-tracking ref. **Re-add the remote deliberately and push one refspec explicitly** — **never** `--all`, **never** `--mirror`.

## 8A.9 · Where the rehearsal corrected §8

§8 is left exactly as written above. These are its defects, each found by running it:

1. **“Replacing the two blobs” is wrong — there are four.** §8.2 was written during wave 1 and never updated after waves 2 and 3 added `quickstart.md` and `llm-bridging.md`. A rewrite scoped to §8.2’s two blobs would have left **489 bytes of disclosed material across 5 lines** in public history, including the third party’s first name used as a person in prose.
2. **§9.6 misstates where quickstart.md came from.** It says `quickstart.md` was introduced in `63ac4df`. Measured: `git rev-parse 63ac4df:specs/001-workshop-curriculum-platform/quickstart.md` fails — the file does not exist in that commit. It was introduced in `d0b3c64` and is carried by 3 commits, not 4.
3. **--replace-text is the wrong instrument, though it does work.** It was run in full as Run A: **208.06 s**, and it did reach zero residue on all 51 literals with the same surgical 4-blob / 5-tree footprint. But getting there required discovering three things §8 does not mention. (a) The rules file is line-oriented, so a multi-line quoted passage cannot be one rule — it must be decomposed into per-line literals. (b) **Not every removed line is safe to use as a rule.** Six of the 57 had to be rejected as too generic to substitute globally across all history — one of them is a 3-character markdown fence occurring 38 times in that file alone; using it as a rule would have corrupted unrelated content in unrelated commits. Each of the six was then individually checked to confirm it carries no disclosure. §8 gives no filtering rule and an operator following it literally would have written a destructive rules file. (c) It produces history containing **\*\*\*REDACTED\*\*\*** marker lines rather than the redacted

prose, so the working-tree redaction remains a separate uncommitted change.

4. **The `--blob-callback` route is better and needs no secret-bearing rules file at all.** §8.2's warning that "*the rules file itself contains the disclosed strings*" — that it must be written outside the repository, never committed, and shredded — is correct as far as it goes, but it is a hazard that can be **designed out** rather than managed. Keying on `blob.original_id` and substituting a pinned redacted file means no artifact of the procedure ever contains the disclosed text. It costs **391.23 s instead of 208.06 s**; that is the whole price.
5. **§8 has no numbers.** It could not tell the operator that this takes about 18 minutes, needs 6 GB of RAM and 10 GB of scratch disk, or that a `git fsck` over the result costs another 94 seconds. A plan that cannot be scheduled is a plan that gets started at the wrong time.
6. **§8 does not mention that five prose citations of 63ac4df in three tracked files go stale** (§8A.5).
7. **§8.4's central claim is now demonstrated rather than asserted** (§8A.6): after a successful `--force-with-lease`, the leaked blob remained fully readable by SHA on the remote, and only a server-side `gc --prune` removed it.
8. **§8.0's decision inputs were partly measurable all along, and nobody had measured them.** Zero forks, zero pull requests, zero page views are facts that materially change the cost/benefit — and the one fact that matters most, clone traffic during the exposure window, **does not exist yet** and will not until 2026-09-02.

## 8A.10 · Recommendation — rewrite, and treat the support request as the substantive step

This is a recommendation, not a decision. The decision is the operator's and §8.0 correctly frames it. But the rehearsal changed the balance, so leaving the recommendation unstated would be a failure to report what was learned.

**The case for leaving history intact.** The material is 4,400 bytes of prose and a name, not a credential. It has been public for hours in a repository with **zero forks, zero pull requests and zero recorded page views** — the realistic probability that a human being has read it is low. A rewrite invalidates 4 commit SHAs, breaks every existing clone, strands five evidence citations, and — on its own — **removes nothing from GitHub's servers**. If the honest answer to "who has

actually seen this” is “nobody”, then a rewrite is ceremony with a real cost and no benefit. §8.0 is right that this is sometimes the correct answer.

**The case for rewriting.** It is not a credential, and that is the argument *for* acting, not against. A leaked token can be rotated in a minute and the exposure ends; a person’s name linked to a dated private business conversation **cannot be rotated, ever**. The asymmetry runs the other way from the usual secrets case. The person carrying the risk is not the person who published it and has no say in the matter. And the cost is now measured rather than feared: **about 18 minutes, 4 commits, one remote ref, 6,237 of 6,246 tree entries untouched, all 9 gitlinks and every helix-deps.yaml pin intact, all 4 tags intact, 98 of 103 commit SHAs intact, git fsck clean**. Because there are no forks and no pull requests, the two things that usually make a rewrite ugly do not exist here. This is close to the cheapest a history rewrite ever gets.

**Recommended: do all three, in this order — and understand that the rewrite is the least important of them.**

1. **Tell the third party.** §8.0 already says this is defensible regardless of what is decided about git, and the rehearsal supports it more strongly: no git operation can undo disclosure of a name, and the person concerned is the only party who can judge what the exposure means for them. **This is the substantive remedy. The other two are hygiene.** Operator’s call, and an agent must not take it.
2. **Rewrite and force-push**, using §8A.3, under explicit §11.4.113 authorization, with the §9.1.5 post-op gate green. The measured cost is low, the blast radius is small and known, and it is the necessary precondition for step 3 — the support request cannot be filed until the first-changed-commit mapping exists.
3. **File the support request** (§8A.7). This is the step that actually removes the content from GitHub’s storage. A rewrite without it leaves all four commits fetchable by SHA for an indefinite period, which the demonstration in §8A.6 shows plainly.

**One thing to do before any of it, because it is free and it may change the answer:** re-run `gh api repos/milos85vasic/vasic/traffic/clones` **on or after 2026-09-02**, when the exposure window finally appears in the data. If it shows unique cloners during the window, step 1 becomes urgent. If it shows none, steps 2 and 3 are cheap insurance and step 1 is still right.

**What would change this recommendation:** evidence that the content is already mirrored, indexed or archived elsewhere. Nothing found so far suggests it is — zero forks, zero page views, zero referrers — but three of those four channels are unmeasurable from here, and “not measured” is not “not happened”.

---

## 8B · The remediation, EXECUTED — 2026-09-01, under explicit operator authorization

**Status: EXECUTED AND FORCE-PUSHED.** This was done to <ext-volume-host>/Projects/vasic and to git@github.com:milos85vasic/vasic.git. §8 and §8A are left **exactly as written**; this section sits beside them and records what running the plan for real produced, including where the live tree had moved out from under §8A’s measurements.

**The authorization (§11.4.113).** Given by the operator in-session, verbatim: *“Rewrite history + force-push”,* with three conditions — *“Make sure no git history or codebase is lost, corrupted or broken! Make sure we have on our side all codebase brought from all upstreams before any force push is performed! Create proper backups too!”* All three were re-verified independently before anything destructive ran (§8B.1). No outward-facing action of any kind was taken: **GitHub Support was not contacted, no issue was opened, and the third party was not contacted.** Those remain the operator’s.

### 8B.1 · Preconditions, re-verified rather than inherited

| Condition                         | How it was verified                                                                                                                    | Result                                                                                                       |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|
| All upstreams present locally     | git ls-remote<br>against all three<br>remote names, read-<br>only; every object id<br>returned was<br>resolved with git<br>cat-file -t | <b>10 remote refs, 9<br/>distinct objects, all<br/>resolved locally. 0<br/>missing.</b> No fetch was<br>run. |
| Backups exist and<br>are complete | for-each-ref + cat-<br>file inside the bare<br>mirror; .git<br>presence and object                                                     | Mirror ../.vasic-<br>history-<br>mirror-2026-09-01.git:<br><b>11 refs, 104 commits,</b>                      |

| Condition                             | How it was verified                                                       | Result                                                                                                                                                                                          |
|---------------------------------------|---------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                       | probes in both<br>hardlinked<br>snapshots                                 | <b>4.0 GB</b> , holds all four<br>leak blobs, all six<br>affected commits, <b>and</b><br>the three dangling<br>blobs and the<br>unreachable a8137db.<br>Both snapshots carry<br>their own .git. |
| Everything<br>committed and<br>pushed | git status --<br>porcelain --ignore-<br>submodules=all; ls-<br>remote × 3 | Umbrella working tree<br><b>clean</b> ; local HEAD =<br>4df8401c32b6 = refs/<br>heads/main ON origin,<br>github <b>and</b> upstream —<br>which are three <i>names</i><br>for one repository.    |
| Gates green                           | bash scripts/pre-<br>push-gates.sh                                        | <b>rc=0, 8/8 PASS, 214 s</b><br>(\$8B.7).                                                                                                                                                       |

Two facts about the tree had **moved since §8A** and both changed the work:

1. **HEAD is 4df8401, not ee3933d**. Two further commits landed — cbdb535 and 4df8401 — and **cbdb535 committed the working-tree redaction**. So the tip was already clean before the rewrite, and the rewrite’s whole job was the four *historical* commits.
2. **.gitmodules now declares 13 gitlinks, not 9**, and the tree at HEAD has **6,260** entries, not 6,246.

## 8B.2 · The pinned replacements, re-derived against current HEAD

§8A’s own instruction was followed: **the rehearsal’s SHAs were not reused**. Each pinned file was rebuilt from scratch as *pre-image plus only the disclosure hunks*, by diffing the pre-image blob against the **current HEAD** blob and selecting hunks by hand.

| File             | Pre-<br>image<br>blob | HEAD<br>blob | Hunks<br>pre→HEAD | Disclosure<br>hunks<br>selected | Unrelated<br>hunks<br>rejected |
|------------------|-----------------------|--------------|-------------------|---------------------------------|--------------------------------|
| RECON.md         | 101e019c              | f4724894     | 4                 | 4                               | 0                              |
| transcription.md | 7c3513d3              | c234dde0     | 4                 | 4                               | 0                              |

| File            | Pre-image blob | HEAD blob | Hunks pre→HEAD | Disclosure hunks selected | Unrelated hunks rejected                                               |
|-----------------|----------------|-----------|----------------|---------------------------|------------------------------------------------------------------------|
| llm-bridging.md | 7801a537       | f94054b7  | 5              | 1                         | 4 — the /<br>api/<br>answer→/<br>api/ask<br>route<br>rename            |
| quickstart.md   | a4aed8a4       | 1c2f577d  | 8              | 1                         | 7 — status,<br>script-path<br>and<br>benchmark-<br>path<br>corrections |

Selecting the whole HEAD blob for the last two would have injected 11 hunks of unrelated later work into four commits dated earlier the same morning — the §8A.8 trap, still live.

| Pinned file  | Bytes   | sha256                                                     |
|--------------|---------|------------------------------------------------------------|
| RECON.pinned | 100,264 | 663fbba60ed81a134d653eaeaa9bd35c06a2464afb5fa4b5f904c9ccc8 |

| LLMB.pinned  | 61,695  | b1371f1f77810930aad21637deb94bb0b272a92e6acacc8cbc1424eef4 |
| QUICK.pinned | 62,652  | 91d33086273443a796558987733f7f5c5812fba0c123fdb48c3a356aa7 |

The independent re-derivation reproduced **57 removed lines / 4,400 bytes** — §8A.1’s figures exactly — and **all four sha256 values are identical to the rehearsal’s**. Nothing was copied across; they were rebuilt and then found to agree. That is the strongest available evidence that the redaction committed at cbdb535 and the content pinned during the rehearsal are the same bytes.

### 8B.3 · Scope correction — the exhaustive scan found SEVEN carriers, not four

§8A.1 recorded each of the 51 usable literals in **exactly one** blob. Re-measured at 4df8401 over **8,185 objects / 6,508 blobs** with --batch-all-objects, that is **no longer true: 7 distinct blobs** carried disclosed literals.

| Blob                                            | Literals        | What it is                                                                                                                                                                                                                                     |

| a58e8494 · efa0cc10                             | 4 · 4           |                                                                                                                                                                                                                                                |

The three extra blobs were confirmed **reachable from no ref and present in no commit tree of any ref or reflog** — dangling objects left by the commit wrapper’s `git add` . over a partially-redacted working tree. **They were never pushed**, because `git push` transfers only objects reachable from the pushed ref, so they were never part of the public exposure. They are recorded because a scan that stopped at §8A’s four blobs would have reported them as absent without ever having looked, and because they are exactly the residue an in-place rewrite must also clear. **filter-repo’s reflog-expire and prune removed all three.**

## 8B.4 · The procedure that was run, with measured wall-clocks

Run **in place** in the live repository — not in a clone — because the tip was already clean, the three dangling carriers only exist locally, and an in-place run is the only one that clears them and leaves a correct checkout. `$W` is a scratch directory **outside** the repository, mode 700.

| Step | Command                                           | Wall-clock |
|------|---------------------------------------------------|------------|
| 0    | preconditions +<br>backup<br>verification (§8B.1) | —          |
| 1    | pre-image / HEAD<br>blob extraction,<br>hunk      | ~1 s       |

| Step | Command                                                                                               | Wall-clock                          |
|------|-------------------------------------------------------------------------------------------------------|-------------------------------------|
|      | classification,<br>pinned-file build                                                                  |                                     |

| 8    | negative control —<br>deliberately wrong<br>lease, <b>must be<br/>refused</b>                         | 210 s (gates re-run by the<br>hook) |
| 9    | git push --force-<br>with-lease=refs/<br>heads/<br>main:4df8401...<br>origin main:refs/<br>heads/main | <b>242 s</b> (204 s of it gate 6)   |

**Total ≈ 13 minutes, peak RSS 560 MB** — under 1 % of this host's 62 GB, far inside the §12.6 60 % cap. The rewrite itself cost **12.54 s against §8A's 391.23 s**: the rehearsal paid for a --no-local clone of a 3.96 GiB pack, whereas fast-export here only ever sees the **104 reachable commits**, and the 1.78 GB private packfile blob of §8A.6 hangs off an unreachable commit it never visits.

The `--blob-callback` route was used, as §8A.9(4) recommends. The callback is a {blob SHA → pinned filename} map with a sha256 assertion per file and an abort on mismatch. **It was verified to contain none of the 51 literals before it was run.** No artifact of this procedure ever held the disclosed text.

## 8B.5 · Verification after the rewrite, before the push

- **Residue: 51 of 51 literals, 0 matches, in 0 blobs**, across all 6,230 blobs under `--batch-all-objects` — which sees unreachable and reflog-held objects, not only what the refs reach. Before the rewrite all 51 matched, in 7 blobs. The scan is the *same script* in both directions, so the before-run is its own positive control.
- **All seven leak-bearing blobs and all six affected commits are unresolvable locally.** `git cat-file -t` returns “*could not get object info*” for 63ac4df, d0b3c64, 96b2988, ee3933d, cbdb535, 4df8401, 101e019c, 7c3513d3, 7801a537, a4aed8a4, 9ddf0b04, a58e8494 and efa0cc10.
- **Tree at HEAD: 6,260 of 6,260 entries byte-identical. Zero changed.** 0 paths added, 0 removed. This is *stronger* than §8A’s “9 changed” and it is correct, not suspicious: the redaction was already committed at cbdb535, so the tip needed no change and only the four historical commits moved. That the change did land was verified separately — each rewritten historical blob is byte-identical to its pinned file, checked with `cmp`, all four.
- **Gitlinks: 13 of 13 unchanged at HEAD; 102 of 102 distinct (path, sha) pairs unchanged across all history.** `helix-deps.yaml` and `.gitmodules` keep their blob SHAs (15dc191f, 830bb3ac). **No submodule, .gitmodules or helix-deps.yaml was touched.**
- **Identity: byte-identical for all 104 commits** — author name, author email, author date, committer name, committer email, committer date and subject, compared as a sorted stream. **98 of 104 commit SHAs unchanged.**
- **All 4 tags unchanged**, still pointing at their original objects — they predate 63ac4df.
- **git fsck clean, rc=0, no output, 5 s. 0 unreachable, 0 dangling, reflog empty.** Object count 8,185 → **7,412**; pack 3.96 GiB → **493.21 MiB**, the difference being 180 unreachable commits, 181 unreachable blobs and 243 unreachable trees that `filter-repo` pruned — **all of them preserved in the mirror backup**, which was not gc’d, pruned or touched.

- Umbrella working tree **clean**; the pre-existing uncommitted content inside the `milosvasic.ru` and `vasic.digital` submodule working trees was **preserved untouched**.

## 8B.6 · The push

`filter-repo` removed the `origin` remote, as §8 predicted; `github` and `upstream` survived. **It did *not* convert remote-tracking refs into local branches this time** — checked, per §8A.8: `refs/remotes/github/main` and `refs/remotes/upstream/main` stayed under `refs/remotes/` and were merely rewritten. `origin` was re-added and the remote configuration verified byte-identical to the pre-rewrite `git config` dump. **No `git fetch` was run at any point after the rewrite.**

**Negative control first (§1.1 paired mutation), against the real remote:**

```
git push --force-with-lease=refs/heads/main:000...000 origin
main:refs/heads/main
! [rejected] main -> main (stale info) rc=1
remote before: 4df8401... remote after: 4df8401... ← UNCHANGED
```

**Then the authorized push:**

```
git push --force-with-lease=refs/heads/
main:4df8401c32b682e5e60693c02daca75799a52c66 \
      origin main:refs/heads/main
+ 4df8401...562ecf9 main -> main (forced update)
```

One explicit refspec. Never `--all`, never `--mirror`, never bare `--force`. **Confirmed from `git ls-remote`, not from push output**, against each remote name independently — all three return `562ecf9cca2d01beaf9ba8bde7474c465f0169ee` for `refs/heads/main`, the same four tags at their original objects, and no other ref. Exactly **one** remote ref was touched.

## 8B.7 · Commit map — six SHAs moved, and the mapping GitHub Support needs

`.git/filter-repo/first-changed-commits` holds one line, which is the value §8A.7's request asks for:

```
old 63ac4df32e5fd40806a50cd38fde8cdc39587c2c → new
fc7574b27c7f9298b05bb55cc5a0ba024cb9da5f
```

| Old      | New      | Subject                                             |
|----------|----------|-----------------------------------------------------|
| 63ac4df3 | fc7574b2 | SpecKit 001 through plan phase...                   |
| d0b3c649 | 7b4df26d | SpecKit 001 through tasks...                        |
| 96b2988e | 4ee9e8de | gates: distinguish ‘could not run’ from ‘failed’... |
| ee3933d4 | b0ab4b44 | gates: defer live-production specs...               |
| cbdb5351 | 25fe585e | feat(platform): workshop curriculum platform...     |
| 4df8401c | 562ecf9c | chore(audit): triage the 82 findings...             |

Six, not §8A’s four, because two commits landed after the rehearsal. **The first four new SHAs are identical to the rehearsal’s**, which independently confirms the pinned content was reproduced byte-for-byte.

**Stale citations, fixed in a normal follow-up commit.** `filter-repo` rewrites old hashes in commit *messages*, never inside blob content, so prose citations survive untouched and dangling. The five §8A.5 named — `helix-deps.yaml` ×2, `scripts/verify-governance-cascade.sh` ×1, `scripts/verify-manifest-pins.sh` ×2 — were repointed at `fc7574b2` with the move recorded rather than silently applied. Re-derivation found **more than the five**: `docs/check-registry.md` ×3 (`d0b3c64/96b2988/ee3933d`), `CONTINUATION.md` ×4, and five `cbdb535` citations in `.environment-assumptions-allow` ×2, `.hardcoded-paths-allow` ×1 and `docs/environment-adaptability/AUDIT.md` ×2 — **17 in 8 tracked files**, all repointed.

**The historical SHAs in §2, §3, §8A and §9.6 of this document are deliberately NOT rewritten.** §8.2 said they would become references to a discarded history and that the document should say so rather than be edited to hide it. It is said here.

**SUPERSEDED BY §11.4 — read this before using any SHA in §8B.** A **second** authorized rewrite ran on 2026-09-02. Every “new” SHA in the table above — `fc7574b2`, `7b4df26d`, `4ee9e8de`, `b0ab4b44`, `25fe585e`, `562ecf9c` — was itself discarded by it and **no**

**longer resolves.** §8B is left exactly as written because it is the record of the FIRST run and falsifying it would be the bluff. **The First Changed Commit the support request needs is now 63ac4df32e5f... → 16cd4ba847de..., not the value above,** and one request now covers both rewrites. The full two-generation mapping is in §11.4.

## 8B.8 · What this did NOT do — state this plainly and do not let it be forgotten

**The force-push removed nothing from GitHub.** §8A.6 demonstrated this rather than quoting it: after a successful `--force-with-lease` on the stand-in remote, 63ac4df still resolved and all **98,599 bytes** of 101e019c were still readable by SHA; only a server-side `reflog expire + gc --prune=now` made them unresolvable. **That is exactly the situation on github.com right now.** All four orphaned commits — 63ac4df32e5fd40806a50cd38fde8cdc39587c2c, d0b3c6493a7f635a0a71d81f049069fb2741ea9c, 96b2988ef61f4adee1bba51ee1c42efcb5f4408e, ee3933d46211d6001ffc23acab480e0cffdc99c6 — and every byte of the four leak blobs **remain fetchable by SHA** from the public repository by anyone who recorded one, and the timing of GitHub's garbage collection is **not the repository owner's to control.**

Three things this rewrite therefore does not achieve, and one it never could:

1. **Only a GitHub Support purge removes the data from their storage.** The request text is prepared at §8A.7 and the first-changed-commit value it needs is in §8B.7. **It has not been sent. It is the operator's to send and no agent may send it.**
2. **Telling the third party remains the substantive remedy** (§8A.10 step 1), and it is likewise the operator's. No git operation can undo the disclosure of a name.
3. **Forks, mirrors, existing clones, and search-engine and archive caches are unreachable by any of this.** Measured 2026-09-01: 0 forks, 0 pull requests, 0 recorded page views — but clone traffic for the exposure window still had not appeared in GitHub's API, so **whether anyone cloned during it remains UNVERIFIED.** Re-run `gh api repos/milos85vasic/vasic/traffic/clones` on or after 2026-09-02.
4. **Nothing can be rotated.** No credential was disclosed. Personal data cannot be reissued or revoked, which is why the purge and the conversation matter more than the rewrite did.

**Anyone holding a clone must rebase, not merge.** Merging an old branch back would reintroduce the deleted content into main.

**Do not record this incident as closed. The rewrite is the cheapest and least important of the three steps §8A.10 recommends, and it is the only one that has been done.**

---

## 9 · Second wave — the ai\_interviewing / workshop matches (2026-09-01, later the same day)

§6 flagged “340 out-of-scope matches” from design-toolkit/ and ai\_interviewing/ as “*a separate incident that has not been assessed, decided, or fixed.*” **This section is that assessment.** It was carried out against a re-derived fleet, not against §6’s figures, and it **contradicts §6 on two points** — recorded rather than quietly corrected, because §6’s numbers were evidence at the time and the tree has moved since.

### 9.1 · The fleet changed under the instrument, so §6’s split no longer holds

Two changes invalidate the §6 attribution:

1. **design-toolkit is now PUBLIC.** Measured this run: `gh repo view vasic-digital/design-toolkit` → `private=false`, and the gate’s own fleet derivation classifies it `public`  
`provider:private=false,push=true`. It is therefore no longer a private *source* at all. **Content sourced from it is not a disclosure and must not be redacted.** Every design-toolkit-attributed match in §6 has ceased to exist as a finding — not because anything was fixed, but because the boundary moved.
2. **.gitmodules grew from 9 gitlinks to 13.** `submodules/LLMProvider`, `submodules/RAG`, `submodules/verdict` and `submodules/passage` were added by other work in flight. All four are **public**, so they joined the scan targets, not the private corpus.

Re-measured split by private source (`verify-content-boundary.sh`, this tree, 2026-09-01):

---

| Private source | §6 / brief figure | Re-measured |
|----------------|-------------------|-------------|
|                | 37                | 216         |

---

| Private source                                 | §6 / brief figure | Re-measured                                            |
|------------------------------------------------|-------------------|--------------------------------------------------------|
| ai_interviewing<br>(private=true,<br>verified) |                   |                                                        |
| workshop<br>(private=true,<br>verified)        | 34                | 16                                                     |
| monetization<br>(private=true,<br>verified)    | 1                 | 0                                                      |
| design-toolkit                                 | 1                 | n/a — repository is<br>PUBLIC; not a private<br>source |
| <b>Total</b>                                   | 232               | 232                                                    |

The total agrees; the attribution does not. Any per-repository figure quoted from §6 or from the brief that prompted this work is **withdrawn**.

## 9.2 · Disposition — three classes, judged individually, not bulk-redacted

### **Class R — REAL DISCLOSURE. 29 matches. Redacted (§9.3).**

Verbatim private code and verbatim private prose.

**Class N1 — NOT A DISCLOSURE: shared authorship boilerplate. 22 matches. Left in place.** Private source ai\_interviewing/platform/qa/challenges/api-challenges.sh; public side scripts/lumen-reindex.sh:63,65, scripts/lumen-index-doctor.sh:54,56, scripts/ollama-vulkan-remediation.sh:67. The matched run is set -uo pipefail followed by the operator's standard usage() comment about printing a script's own header block so --help cannot drift out of sync with it. It is a house style the same author writes into every script he owns, on both sides of the boundary. It describes the **public** script's own behaviour and discloses nothing whatsoever about the private repository's content. Redacting it would delete a correct explanatory comment from three working public scripts to conceal the fact that their author writes comments the same way twice.

**Class N2 — NOT A DISCLOSURE: the public file is the ORIGINAL. 181 matches. Left in place.** Private sources are ai\_interviewing/docs/project-deep-dives/\*.md and their .pdf renders; public sides are the live website product pages \_content/products/\*.md, the \_analysis/

content-briefs/\*, \_analysis/IMPLEMENTATION-REPORT.md, \_analysis/top20/\*, vasic.digital/\_article\_src/en/helixtrack-core.md and its rendered .html, submodules/containers/docs/test-coverage.{md,html}, submodules/LLMProvider/pkg/discovery/discovery.go, and the OCR text captured from screenshots of those same public pages under \_tests/evidence/\*\*.

**The copy direction is measured, not assumed, and it runs public → private.** First-commit dates:

| Public side                                                                                                 | Added     |
|-------------------------------------------------------------------------------------------------------------|-----------|
| _content/products/{HelixConstitution,HelixQA,HelixTrack,HelixTranslate,task_bridge,Qemu-Utills,HelixLLM}.md | 2026-08-0 |
| _analysis/content-briefs/{HelixConstitution,HelixTerminator}.md                                             | 2026-08-0 |
| _analysis/IMPLEMENTATION-REPORT.md, _analysis/top20/ATMOSphere-*.readme.txt                                 | 2026-06-2 |

Every public target predates its private counterpart — by five days in the product-page group and by seven weeks in the \_analysis/ group. The private ai\_interviewing deep-dives are **interview-preparation notes that reuse the operator’s own already-published marketing and product copy**. The matched text is that copy: product taglines, feature descriptions, and public github.com URLs.

Redacting these would mean deleting the operator’s **live public website content** in order to hide text that was public first and that the private repository copied *from* it. That is the over-redaction failure the gate’s own header warns about — 24,963 naive hits whose top thirty were all legitimate. **No action taken, and none should be.**

The \_tests/evidence/\*\*/\*.ocr.txt files deserve one extra sentence: they are OCR output from screenshots of the already-published pages. They cannot disclose anything the rendered public page does not already show.

**9.3 · What was changed in this wave (containment)**

Working tree only. **Nothing was committed, pushed, tagged, or rewritten.**

| File                                          | Line(s) | Was                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Now                                                                                                                                                                                                                                                                                     |
|-----------------------------------------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| docs/<br>workshop-<br>curriculum/<br>RECON.md | 421–425 | <p>A fenced ``sql block reproducing the <b>verbatim</b> query text</p> <p>ofstore.Searchfrom privateai_interviewing/platform/backend/internal/store/store.go  Path-only pointer to the private file plus a <b>functional description</b> – three content tablesUNION ALLed, boundLIKEpatterns over a few short columns, fixed-length excerpt, bound row limit. The finding (naive multi-wayLIKE, no ranking, no FTS, no semantics, titles only) is stated in full immediately after, unchanged.    docs/workshop-curriculum/RECON.md 474–479  The <b>verbatim</b> header comment of privateai_interviewing/scripts/render-diagrams.sh, including the quoted phrase about the validator-safe embed   Path-only pointer plus the reasoning <b>restated independently</b>: the §11.4.168 export check counts embedded raster images, so a vector-only diagram scores zero on it; raster is load-bearing, vector supplementary.    docs/workshop-curriculum/RECON.md 503–505  An explicit quotation, in quotation marks, of the anti-bluff rule in the header of privateai_interviewing/</p> | <p>Path-only pointer plus an independent description: throwaway input, round-trip bit-for-bit check, then deliberate damage to one part with a required rejection. The §1.1 paired-mutation argument — that the green round trip is not evidence on its own — is preserved in full.</p> |

| File | Line(s) | Was                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Now |
|------|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----|
|      |         | platform/qa/helixqa/run-suite.sh  Path-only pointer plus the rule <b>**restated in different words**</b> : a bank counts as passing only if it terminated successfully <b>*and*</b> left evidence, so neither a skip nor an assertion-free run scores as a pass.    specs/001-workshop-curriculum-platform/quickstart.md  315–317  Two runs of <b>**verbatim prose**</b> from the privateworkshopsubmodule's governance carriers (AGENTS.md:89–93and its three siblings) describingscripts/self-test.sh` |     |

**On the workshop carriers specifically.** §11.4.157 propagates governance carriers verbatim **between carriers**, and a carrier sentence appearing in two carriers is not a leak. That exemption does **not** reach this case: the destination here is `quickstart.md`, a public spec document, not a carrier, and the copied text is the workshop project's own project-specific prose, not inherited constitution text. The already-public filter confirms it independently — the run does not appear in any second public repository, so it was never exonerated. It is private prose in a public file, and it was redacted as such.

## 9.4 · Personal data — swept again, and this wave found one more

**No real name is written anywhere in this document, and none was written into any file changed by this wave.**

- **The third party's surname: 0 occurrences in any tracked file**, in any form. Probed directly (surname alone), reversed (Surname Firstname) and comma-reversed (Surname, Firstname) against a concatenation of every tracked text file in the umbrella. All three probes returned zero. §7's result holds.
- **A general sweep found no other person.** Every capitalised bigram in the private prose corpus — all three private repositories'

Markdown and text plus the notes PDF, 42,886 lines — was intersected with the tracked public corpus. **68 bigrams overlap and every one of them is a product, brand, or technology name** (cross-platform toolkits, protocol names, container tooling and model-hub vendors — deliberately described rather than quoted, see the note below). No person's name is among them. A Cyrillic name sweep returned nothing.

- **One new finding, now fixed.** specs/001-workshop-curriculum-platform/research/llm-bridging.md:510 used the third party's **first name** as a named speaker in a constructed example question for the “misattributed speaker” test class. This is **not** the accepted filename baseline of §2 — it is the name used as a person in prose, which attributes participation in a private session to an identifiable individual. Replaced with the role reference “*the second speaker*”. The test class and its FR-005 link are unaffected. The file now contains **0** occurrences.
- **One occurrence left in place, and flagged for the operator rather than decided by an agent.** specs/001-workshop-curriculum-platform/contracts/http-api.md:288 carries the first name inside a JSON example chapter “title”. It is the recording artifact's own name, so it falls inside the §2 baseline — but it is worth the operator's attention because it is the one place where that name would be **served by the API and rendered on a page**, rather than merely naming a file. §2 already records that renaming the artifact in the private submodule is the fix and that it is his call, not an agent's. That remains true here.

## 9.5 · Identified, deliberately NOT redacted, and recorded as a judgement call

docs/workshop-curriculum/RECON.md §2.3 also carries an **API route table** (the endpoint list of the private reference implementation) and a **SQLite table-and-index listing**. Both are derived from private code, and **neither is a gate match** — they are not prose-shaped, and the gate's header declares this limit openly: “*Private code copied into a public repository is outside this instrument and is not claimed to be covered.*”

They were left in place because they are the structural **shape** the specification is built from, and RECON.md's §2 exists to specify the workshop platform by reference to that implementation. Removing them would destroy the finding rather than redact it. This is a judgement call, it is a weaker one than the four redactions above, and

it is written down so the operator can overrule it cheaply — deleting the route table and the schema listing costs the document less than deleting the SQL did.

## 9.6 · This wave is containment too, exactly like the first

Everything §3 says applies unchanged. **The second-wave content is in the same four public commits and in every commit since.** docs/workshop-curriculum/RECON.md and specs/001-workshop-curriculum-platform/quickstart.md were both introduced in 63ac4df on a public remote; research/llm-bridging.md likewise. Redacting the working tree does not remove any of it, and **§8's remediation plan is unchanged, still PREPARED, still NOT EXECUTED, and still NOT AUTHORIZED.** A history rewrite plus force-push requires explicit per-session operator authorization under §11.4.113 and has not been given.

---

## 10 · Third wave — the name class, swept for the first time (2026-09-01, later still)

**Result up front: 125 name-class rows, 20 distinct names by digest, and NOT ONE of them is a person. Zero redactions. Nothing was changed in any public file.** The reasoning is below, and it is the reasoning that matters here — the gate is working correctly and its output is correctly red; what it found in this class is not a disclosure.

### 10.1 · Why this class had never been swept

scripts/verify-content-boundary.sh gained a **name-class detector today**, after waves 1 and 2 had already run. Neither earlier pass could have seen this class: it did not exist. §9.4's personal-data sweep was a hand-built probe over capitalised bigrams; this is the same idea promoted into the gate, run every time, with the fleet derived rather than assumed. **A class that was previously unswept is not the same as a class that was previously clean**, so it was treated as unswept and triaged from zero rather than compared against §9.4's conclusion.

## 10.2 · How the detector builds a candidate, and where its false positives come from

It writes no name down anywhere. Candidates are DERIVED each run by two independent routes:

- **Route (a) — git identities of the private repositories.** These are person names *by construction*; no heuristic is involved. Identities that are also git identities of a PUBLIC repository are subtracted in both orders, which is how the repository owner's own name is excluded without a list.
- **Route (b) — runs of 2–3 consecutively capitalised tokens in private prose, keeping only those whose every token is rare in lowercase** across the corpus (rank  $\leq$  --name-rank 2000 **and** count  $\geq$  --name-mincount 5 makes a token “ordinary”).

**Route (a) contributed ZERO of the 125 surviving rows** — verified by inspecting the private-source column of every row: not one is the gate's own <git identity> marker; all 125 carry an ordinary private FILE path. Every finding in this wave therefore came from route (b), which the gate's own header already identifies as the heuristic half.

## 10.3 · Method — how each of the 125 was identified without disclosing anything

The gate withholds the matched text by design and prints personal name #<digest> plus the public file:line. That discipline was preserved: **no name, and no matched token run, is written into this document.**

Identification was done locally instead. The digest is a small polynomial hash of the lowercase key, computed in the gate at the line beginning `awk -F'\t' ... h($5)`. Re-implementing that hash and the emitter's N-run construction (2–3 consecutively capitalised tokens, folding every non-alphanumeric to a separator, accumulating across line breaks) makes each digest resolvable against the public line it was reported at. Re-derive it the same way:

```
bash scripts/verify-content-boundary.sh > /tmp/gate.txt 2>&1 #
    exit 1 expected
# then, for a row reported as <pubfile>:<line> #<digest>:
#   read that public line and rebuild its capitalised 2/3-token
#   runs,
#   hashing each with the gate's own h() to find which run the
#   digest names.
```

**Result: 125 of 125 rows resolved at their exact reported file:line, and the 20 digests map to 20 distinct keys with no hash collision** (checked: no digest resolves to more than one key). Nothing was left as “could not determine”.

## 10.4 · Disposition — 125 FALSE POSITIVES, 0 real names, 0 redactions

All 20 digests resolve to a **product, brand, technology, jurisdiction adjective, protocol header, web-performance metric, repository name, or a generic document heading**. Described without quoting them, so this document stays inert:

| Rows | What the digest actually names                                                                | Where                                                                |

| 1    | this repository's <b>own submodule name</b>                                                       | helix-deps.yaml:365                                                                      |
| 2    | that same submodule name plus a <b>placeholder word</b> , bridged across a blank line and a fence | docs/workshop-<br>curriculum/<br>RECON.md:211                                            |

**No file was edited. No name was redacted, because no name was found.** Redacting any of these would delete correct technical prose — product comparisons, a distribution matrix, a provider list, a vector-store enumeration — to conceal words that are not personal data. That is the over-redaction failure §9.2 already warned about, and the standing instruction to fix what is found does not license fixing what is not broken.

**10.5 · The two highest-exposure groups, called out individually**

**The 8 rows sourced from the private workshop submodule — the most sensitive class in this tree — are all false positives, and one of them is not even about the workshop.**

| Rows | Public destination                    | What it is                                                                                                                                                                             |
|------|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5    | specs/.../research/transcription.md   | the model-hub brand of §10.4 row 1. The private-side source path happens to be a workshop/chapters/01/... file, but the MATCHED TEXT is a vendor name in a table of model provenances. |
| 1    | helix-deps.yaml:365                   | the submodule’s own name, in this repository’s dependency manifest. It is the manifest naming its own dependency.                                                                      |
| 2    | docs/workshop-curriculum/RECON.md:211 | RECON.md quotes the workshop README’s <b>entire current content</b> inside a fenced block — a title line                                                                               |

| Rows | Public destination | What it is                                                                                                |
|------|--------------------|-----------------------------------------------------------------------------------------------------------|
|      |                    | and a placeholder word. §10.6 explains why the detector joined tokens across the blank line between them. |

No curriculum text, no recording material, and no participant is involved in any of the eight.

**The 6 rows in the PUBLIC, separately-published submodules/RAG/README.md are all false positives.** Both cited lines (351, 426) enumerate three vector-database products the module’s hybrid retriever can sit on, written as a slash-separated adapter list and as a comma-separated backend list. The token folding turns A/B/C and A, B, C into adjacent capitalised runs, which is exactly the shape a name has. **submodules/RAG/README.md was NOT modified** — no edit, no commit, no gitlink bump. Nothing needs to be published for this repo.

## 10.6 · Suggested detector tightening — measured, not guessed; the gate was NOT edited

scripts/verify-content-boundary.sh is another agent’s file and **was not touched**. These are proposals with their measured yield against this run’s own 125 rows. Each would need a paired mutation under §1.1 proving a seeded real name still survives it, before adoption.

1. **A hard-separator break in the N pass — the highest-yield and the cheapest in recall.** The emitter folds *every* non-alphanumeric to a separator, which is right for the prose class (it defeats re-wrapping) but wrong for names: it fuses unrelated proper nouns listed with /, ,, |, ;, backticks or brackets into a single “name”. Recording a hard-break flag at those positions and requiring no hard break *between* the tokens of an N run would drop **82 of the 125 rows (66%)**, clearing 7 digests outright. A given name and a surname are not separated by a slash, a pipe, a semicolon, a backtick or a bracket, so recall cost is nil for those. **The comma is the one to think about:** it alone accounts for 15 of the 82, and Surname, Firstname is a real name form — but the detector already matches both orders, so treating the comma as hard would lose

that form unless it is excepted for the 2-token reversed case.

Excluding the comma entirely still yields **67 rows**.

2. **No bridging across a blank line, in the N pass only.** A name never spans a paragraph break. Worth **3 rows**, including 2 of the 8 workshop-sourced ones, at zero recall cost.
3. **--name-rank 2000 is too small for this corpus, and an absolute rank is not scale-free.** Measured over the private prose corpus (941,648 tokens, tracked \*.md/\*.txt in the three private repositories): the tokens that made these keys look “rare” sit at ranks 2072–12227 — e.g. one occurs 65 times at rank 2072, another 58 times at rank 2286, another 62 times at rank 2164. Words occurring dozens of times are not rare; they merely fall past an absolute cutoff. A **count floor** (“any token occurring  $\geq N$  times in the corpus is ordinary”, independent of rank) is scale-free where a rank cutoff is not: at  $N = 20$  it would clear **13 of the 20 digests**. Combined with proposal 1 it leaves **6 rows** of the 125. This is the proposal with a real recall tradeoff — a surname that is also a common word would be demoted — so it is the one that most needs its mutation before it ships.
4. *Not recommended without more evidence:* treating an intra-word hyphen as a hard break would clear 7 further rows but would break double-barrelled given names, which is a recall loss in exactly the class the detector exists for.

## 10.7 · Copy direction was still verified, because it is load-bearing for 85 of the rows

Even though the name class produced no disclosure, the copy direction was measured rather than assumed for the `_content*/_analysis/` glossary cluster — **85 of the 125 rows** — because if any row there HAD been real, redacting it would have deleted live public website content. First-commit dates, this repository vs `ai_interviewing`:

The public files predate their private counterparts by five days to seven weeks, so the public file is the **ORIGINAL** and §9.2's Class N2 finding holds unchanged for the name class too. These rows are doubly not-a-disclosure: the matched text is not a name, *and* the flow runs public → private.

## 10.8 · This wave changed nothing, so there is nothing new to contain — but §3 still stands

No public file was edited in this wave, so it adds no containment and removes no exposure. **That does not make the incident smaller.** Everything §3 and §9.6 record is unchanged: the wave-1 and wave-2 material is still in the public commits and in every commit since, and working-tree redaction never removed it. **§8's remediation plan is untouched by this wave — still PREPARED, still NOT EXECUTED, still NOT AUTHORIZED.** A history rewrite plus force-push is destructive, requires explicit per-session operator authorization under §11.4.113, and that authorization has not been given.

## 10.9 · One thing the operator should know about THIS file

docs/content-boundary-incident-2026-09-01.md is **untracked**, so git ls-files does not see it and the gate never scans it. That is why this wave's edits cannot move the gate's count, and it is what makes the before/after below a clean A/B. It has a consequence: **§9.4 wrote one of this wave's false-positive brand pairs into this document in plain text.** If this file is ever committed — and the commit wrapper runs git add ., which would stage it — that line will start producing a name-

class row of its own. §10.4 above is written descriptively for exactly this reason. Either leave the file untracked, or reword that §9.4 line before committing it.

---

## 11 · Fourth wave — the third party's FIRST name, and the deferred decision reversed (2026-09-02)

**Status: WORKING TREE REDACTED AND COMMITTED.**  
**HISTORY REWRITE — see §11.4.** This wave concerns the one identifier of that person that the first rewrite deliberately left standing: the **first name**, carried inside the recording's own filename. The name is **not written anywhere in this document**, here or above, and must not be.

### 11.1 · Why §2 deferred this, and why that reasoning expired

§2 recorded the filename as *“Not treated as a disclosure, deliberately”*, and the judgement was sound **at the time it was made**. The argument was explicit: the filename carries a **first name only**, while the same documents carried the person's **full name** in prose alongside a date and a subject. Removing the weaker identifier while the stronger one stood three lines away would have accomplished nothing.

**§8B removed the stronger one.** Once the full name and the verbatim quotations were purged from history and force-pushed, the premise of §2's deferral no longer held: the first name became **the only remaining identifier of that person in a public repository**. A decision correctly taken against one set of facts had to be re-taken against another. It was put to the operator with both halves of the trade stated, and the decision given was, verbatim:

*“Redact + second rewrite”*

That is also the §11.4.113 authorization for the second force-push. It is recorded here rather than paraphrased, because an authorization that cannot be quoted is not an authorization.

## 11.2 · The true reference set — measured, and smaller than the brief predicted

The brief that opened this wave estimated **19 references across 5 tracked files**. That figure is **wrong, and wrong in the safe direction** — it counted every mention of the recording and of the notes PDF, including the many already written in the elided ...Recording.mp4 and ... - Notes by Gemini.PDF forms, which carry no name at all.

Re-derived at HEAD with a case-sensitive **whole-word** `git grep` over all tracked files, the name occurs on exactly **9 lines in 4 files** — one occurrence per line, **9 in total**:

| File                                                             | Lines          | What each is                                                                 |
|------------------------------------------------------------------|----------------|------------------------------------------------------------------------------|
| docs/workshop-curriculum/RECON.md                                | 62, 63, 64, 65 | the four chapters/01/ entries of the §1.1 “complete — every path” tree       |
| specs/001-workshop-curriculum-platform/spec.md                   | 17             | the “Verified Starting State” table row naming the source recording          |
| specs/001-workshop-curriculum-platform/quickstart.md             | 83, 284        | two <b>RUNNABLE NOW</b> shell commands with the literal path                 |
| specs/001-workshop-curriculum-platform/research/transcription.md | 154, 1074      | a captured ffmpeg invocation, and the Title: line of captured pdfinfo output |

The **fifth** file the brief detected is **this document**, at §2 — where the filename appears in its already-elided form and the name does not appear at all. It needed no redaction and received none.

Three further facts, measured rather than assumed:

- **No second spelling.** Whole-word searches for the all-lowercase and all-uppercase variants return **0** across every tracked file. A case-**insensitive** search returns hundreds of files and is worthless here: the token is four characters long and is a common substring

of ordinary English and Spanish words throughout `_content*/`. Substring matching on a four-character name is not a detector, it is noise.

- **Nothing untracked carries it.** `docs/session-instruction-audit-2026-09-01.md` and `specs/002-knowledge-areas-deep-linking/` were scanned: **0**.
- **The surname is already gone**, as §8B left it. This wave adds nothing on that front.

## 11.3 · The redaction — 9 substitutions, two forms, and why each was chosen

Committed to the working tree first, as a normal commit, **before** any history operation.

| Where                                                | Form used                          | Why that form                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|------------------------------|------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| quickstart.md:83,<br>:284 ×2 | workshop/chapters/<br>01/*Recording.mp4<br>(unquoted glob) | <p>invasive edit available and makes the block internally consistent.</p> <p>These two are marked <b>RUNNABLE NOW</b>. An ellipsis would have turned a runnable command into a broken one — “<i>a redaction that destroys the finding is a failed redaction</i>”. The glob keeps them runnable and is not a loss of precision: that directory holds exactly one <code>*Recording.mp4</code> and one <code>*Recording.mp4.sha256</code>, and a glob expansion is not subject to word splitting, so the embedded spaces are handled correctly without quoting.</p> |

**No document lost a finding.** The recording remains addressable three ways with no filename at all: by directory (`workshop/chapters/01/`), by chapter slug (`01-ai-workflows`), and — for any passage inside it — by the pid that `contracts/passage-contract.md` defines. Each of the four files carries a short, explicit **Redaction** note so the ... reads as a deliberate elision and never as a truncated path; each points back here.

The substitution was applied by a script that **derives the token from the text at run time** and never contains it. There is no rules file, no allow-list, and no artifact of this wave that holds the name.

11.4 · The SECOND rewrite — executed 2026-09-02, in place, under §11.4.113 authorization

**Status: EXECUTED AND FORCE-PUSHED.** This was done to <ext-volume-host>/Projects/vasic and to git@github.com:milos85vasic/vasic.git. §8, §8A and §8B are left exactly as written.

Preconditions, re-verified rather than inherited.

| Condition                                         | How verified                                         | Result                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| In-flight work of another session preserved       | index snapshot to a 700 scratch dir outside the repo | <b>A staged, unrelated submodules/constitution pin</b>                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Condition | How verified | Result                                                                                                                                                                                                                                                                                                                                                                          |
|-----------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           |              | <b>bump</b> (f16ea77 → f5876a3, in helix-deps.yaml <b>and</b> the gitlink) was sitting in the index. filter-repo ends with reset --hard, which would have discarded it. It was saved out and restored byte-for-byte afterwards, and it was <b>deliberately kept out of every commit this wave made</b> — moving the constitution pin is not this wave's authorization to spend. |

**Scope correction — the exhaustive scan found EIGHT carriers, not four.** A `git grep` at HEAD sees only the tip. `git cat-file --batch-all-objects` sees every object, reachable or not:

| Blob                                 | Path                                   | Occ.      | Introduced by                        |
|--------------------------------------|----------------------------------------|-----------|--------------------------------------|
| f4724894                             | docs/workshop-curriculum/RECON.md      | 4         | fc7574b2                             |

| <b>5e9f9155</b>                      | <b>contracts/http-api.md</b>           | <b>1</b>  | 7b4df26d                             |
| <b>Total</b>                         | <b>5 distinct paths</b>                | <b>14</b> |                                      |

contracts/http-api.md is the one that matters: it carried the name in a JSON example at line 288 in 7b4df26d, and a **later edit removed that line**. So the file is clean at HEAD and **invisible to every HEAD-scoped search** — the §11.2 reference set could not have found it. Only the all-objects scan did. All eight carriers were **reachable**; unlike the first run, no staged-only intermediates were left behind.

The scan is its own control: **the identical script**, run before and after, and the two literals it searches — the exact `Milos teaching <token> AI workflows disclosure form` and the **bare token under word boundaries** — returned **the same 8 blobs and the same 14 occurrences** before. That equality is itself a finding: **every occurrence of the bare token anywhere in the repository is part of the disclosure form**. There is no lexical coincidence to judge.

**Procedure and measured wall-clocks.** Run **in place**, not in a clone: the tip was already clean after 9c89ae2, so only historical commits needed to move, and an in-place run is the only one that also leaves a correct checkout.

| Step | What                                                                 | Wall-clock                     |
|------|----------------------------------------------------------------------|--------------------------------|
| 0    | backup mirror + precondition verification                            | ~1 s (hardlinked)              |
| 1    | pre-rewrite residue baseline, <b>all 6,250 blobs / 7,465 objects</b> | <b>11.47 s</b>                 |
| 2    | build 8 sha256-pinned redacted replacements + the callback           | ~1 s                           |
| 3    | git filter-repo --force --blob-callback ...                          | <b>7.72 s, peak RSS 601 MB</b> |
| 4    | post-rewrite residue scan, <b>all 6,247 blobs / 7,443 objects</b>    | <b>11.52 s</b>                 |
| 5    | tree / gitlink / identity / tag comparison                           | ~4 s                           |
| 6    | git fsck --full                                                      | <b>5.18 s</b>                  |

| Step | What                                                             | Wall-clock |
|------|------------------------------------------------------------------|------------|
| 7    | bash scripts/pre-push-gates.sh<br>(baseline, before the rewrite) | 213.77 s   |

Peak RSS **601 MB** — under **1 %** of this host’s 62 GB, far inside the \$12.6 cap. The `--blob-callback` route was used, as §8A.9(4) recommends. The callback is a {blob SHA → pinned filename} map with a sha256 assertion **re-checked on every substitution**; it holds only ids, filenames and digests. **The callback, all eight pinned files and the manifest were each verified to contain zero occurrences of the token before the rewrite ran.** No artifact of this procedure ever held the disclosed text.

#### Verification after the rewrite, before the push.

- **Residue: 0 blobs, 0 occurrences** of either literal across all **6,247 blobs / 7,443 objects** under `--batch-all-objects`. Before: **8 blobs, 14 occurrences**.
- **All 8 carrier blobs and all 9 affected commits are unresolvable locally** — `git cat-file -t` returns “*could not get object info*” for every one, including the pre-first-rewrite SHAs 63ac4df, d0b3c64, 96b2988, ee3933d, cbdb535, 4df8401.
- **Tree at HEAD: 6,260 of 6,260 entries byte-identical. Zero changed.** 0 paths added, 0 removed. Correct rather than suspicious: the redaction was already committed at 9c89ae2.
- **Gitlinks: 13 of 13 unchanged at HEAD; 104 of 104 distinct historical (path, sha) pairs unchanged** (compared against the untouched backup mirror, not against a memory of them). `helix-deps.yaml` keeps blob 069f4972 and `.gitmodules` keeps 830bb3ac. **C9 and verify-manifest-pins.sh are unaffected by construction** — a gitlink points *outward*, into an object graph this rewrite never enters.
- **Identity byte-identical for all 107 commits** — author name, email, date, committer name, email, date and subject, compared as a sorted stream. **98 of 107 SHAs unchanged; 9 moved.**
- **All 4 tags unchanged**, still at their original objects — they predate 63ac4df.
- **git fsck --full rc=0, no output. 0 unreachable, 0 dangling, reflog empty.** Objects 7,465 (7,412 packed + 53 loose) → **7,443 packed, 0 loose; pack 493.21 → 493.28 MiB.**

- Umbrella working tree otherwise unchanged; the pre-existing dirty state inside the workshop and submodules/constitution submodule working trees was **preserved untouched**.

**Commit map — nine SHAs moved, and the mapping GitHub Support needs.** filter-repo **composed** this run's map with the first run's, so the left column is the **original public** SHA in every row, not the intermediate one. That is what makes a **single** support request cover **both** rewrites:

|                                         |                                 |             | elide the first<br>name... |

**First Changed Commit, as git filter-repo reports it in .git/filter-repo/first-changed-commits:**

```
old 63ac4df32e5fd40806a50cd38fde8cdc39587c2c → new
16cd4ba847dea301e0bb308a9d538cbd6328f13e
```

**This one value replaces §8B.7's.** The operator now sends **one** request covering both rewrites; §8A.7's prepared text needs <NEW-SHA> filled with 16cd4ba847de... and its orphan list extended (below).

**Stale citations, re-derived rather than assumed — 20 occurrences in 8 tracked files.** filter-repo rewrites old hashes in commit *messages*, never inside blob content, so prose citations survive untouched and dangling. The first run predicted 5 and found 17; this run found **20**, in the same class and one file wider: helix-deps.yaml ×3, scripts/verify-governance-cascade.sh ×2, scripts/verify-manifest-pins.sh ×3, docs/check-registry.md ×3, .environment-assumptions-allow ×2, .hardcoded-paths-allow ×1, docs/environment-adaptability/AUDIT.md ×2, CONTINUATION.md ×4. All 20 were repointed and **every replacement SHA was confirmed to resolve**. The citations that already carried a “cited as 63ac4df until 2026-09-01” note now record the **two-generation chain**, because a note that hides the second move is the same defect as a dangling SHA.

**Deliberately NOT repointed: every SHA inside §8A and §8B of this document.** Those sections are the record of the first run and were true when written. Editing them to look right in hindsight is precisely the bluff §11.4.6 forbids. §8B.7 instead carries a **forward pointer** to this section, so nobody can read a superseded value as current.

## 11.5 · The push

filter-repo removed the origin remote, as it did the first time; github and upstream survived. It **did not** convert remote-tracking refs into local branches — checked, per §8A.8: refs/remotes/github/main and refs/remotes/upstream/main stayed under refs/remotes/ and were merely rewritten. origin was re-added and the remote configuration verified **byte-identical** to the pre-rewrite git config dump, pushurl included. **No git fetch was run at any point after the rewrite** — a

fetch from the un-rewritten remote re-imports the very objects the rewrite removed, which is why the explicit `--force-with-lease=<ref>:<sha>` form is used: it needs no remote-tracking ref and therefore no fetch.

Two commits were pushed, not one: f7cad55 (the redaction) and 2d629e9 (this record plus the 20 repointed citations). Both were built and verified before either was sent.

### **Negative control first (§1.1 paired mutation), against the real remote:**

```
git push --force-with-lease=refs/heads/main:000...000 origin
main:refs/heads/main
! [rejected] main -> main (stale info)      rc=1      (215.44 s,
gates re-run by the hook)
remote before: 9dcfc41...    remote after: 9dcfc41...  ← UNCHANGED,
confirmed by ls-remote
```

### **Then the authorized push:**

```
git push --force-with-lease=refs/heads/
main:9dcfc41c306da085963bb92032f808a5f3236d2a \
      origin main:refs/heads/main
+ 9dcfc41...2d629e9 main -> main (forced update)  rc=0
(239.28 s, 203 s of it gate 6)
```

One explicit refs spec. Never `--all`, never `--mirror`, never bare `--force`. **Confirmed from git ls-remote, not from push output**, against each of the three remote *names* independently — all return 2d629e93e92a36a89ea29abf2ecf5ceb49d75630 for refs/heads/main, the same four tags at their original objects, and **no other ref**. Exactly **one** remote ref was touched.

**The project commit wrapper was NOT used, anywhere in this wave.** It runs `git add .` and pushes submodules as well as the root, which in the first run redeployed two live production websites as a side effect. Every commit here was `git commit --only` with an explicit pathspec, and every push was a single explicit refs spec to the umbrella. **No submodule was committed, pushed or bumped, and `_tools/deploy-langs.sh` was never invoked.** The 13 gitlinks at HEAD are the same 13 that were there before this wave started.

## 11.6 · What this did NOT do — the same four facts, and they have not changed

The force-push removed nothing from GitHub. §8A.6 demonstrated this rather than quoting it: after a successful `--force-with-lease` on the stand-in remote, the orphaned commit still resolved and every byte of the leak blob was still readable by SHA; only a **server-side** `reflog expire + gc --prune=now` made them unresolvable.

The orphan list has grown, and the operator must send one request covering all of it. Eight further commits were orphaned by this push, and every one of them carried between three and five of the eight name-bearing blobs:

| Newly orphaned by the 2026-09-02 push    | Carrier blobs in its tree |
|------------------------------------------|---------------------------|
| fc7574b27c7f9298b05bb55cc5a0ba024cb9da5f | 3                         |
| 7b4df26d5684cadbf30a6b7a8ea314e3986a4f34 | 5                         |
| 4ee9e8ded660... (b0ab4b44's parent)      | 5                         |
| b0ab4b4470578300a1335a21f9dd09c93e5578a6 | 5                         |
| 25fe585ee6fd316fec2566b3bae0de0bc75bc0a4 | 4                         |
| 562ecf9cca2d01beaf9ba8bde7474c465f0169ee | 4                         |
| 203061dcb8dd064f394da932ef4e2aba7a814789 | 4                         |
| 9dcfc41c306da085963bb92032f808a5f3236d2a | 4                         |

Those are **in addition to** the four orphaned by the 2026-09-01 push (63ac4df, d0b3c64, 96b2988, ee3933d), which carried the **full** name and the verbatim prose and are **still fetchable by SHA** because no purge has been run. 9c89ae2d1e11... is **not** on the list: it was created and rewritten locally and never pushed.

1. **Only a GitHub Support purge removes any of it from their storage.** Text at §8A.7; the value it needs is 63ac4df32e5f... → 16cd4ba847de... (§11.4), and the orphan list is the four above plus the eight here. **It has not been sent. It is the operator's and no agent may send it.**
2. **Telling the third party remains the substantive remedy.** A name cannot be rotated. Two rewrites do not undo a disclosure; they only stop it continuing.
3. **Forks, mirrors, existing clones, and search-engine and archive caches are unreachable by any of this.** The clone-traffic question §8B.8 left open is now answerable — `gh api repos/milos85vasic/`

basic/traffic/clones covers the 2026-09-01 exposure window from 2026-09-02 onward. **This wave did not run it**; it is a read-only provider query and it is the cheapest evidence available.

4. **Nothing can be rotated.** No credential was involved in either wave.

**Anyone holding a clone must rebase, not merge** — twice over now. Merging an old branch back would reintroduce the deleted content into main.

**The incident is still not closed.** Two of the three steps §8A.10 recommends — the purge request and the conversation — remain undone, and they are the two that matter.

---

## 12 · Fifth wave — the 4,249 triaged in full (2026-09-02)

**Status: NO REDACTION. NOTHING WAS FOUND TO REDACT.** No public file was edited in this wave. `.content-boundary-allow` was **not** touched and `scripts/verify-content-boundary.sh` was **not** touched. The gate still exits **1**, and it should.

§“Wave 4” closed with the name 57 figure marked *“unfinished business ... a known open item, not a pass.”* This wave closes that item and, for the first time, adjudicates the **prose** class as well rather than only its two largest sub-clusters. **The answer to the question the operator actually asked — is anything private genuinely exposed right now — is NO, and the evidence is below.**

### 12.1 · Reproduced first, judged second

`bash scripts/verify-content-boundary.sh --json re-run 2026-09-02` against the working tree at e432703. **Exit 1. 4,249 surviving matches — prose 4,002, short 190, name 57. 0 undetermined.** Identical to the wave-4 figure in every class, so nothing moved under the instrument between the two runs and this wave’s triage describes the same corpus wave 4 measured. Derived exonerations that run: 978 long + 2,558 short path-mask shingles, 1,469 already-public keys (prose 1,400, short 55, **name 14**), 164 name candidates, 11 public git identity forms subtracted, name frequency floor **39** occurrences over **1,581,317** private prose tokens, **0** name path-reference pardons, 9 declared pairs pardoning 4,187 matches, 107 files not indexed.

**The 4,249 is not comparable to 377 / 232 / 203 / 367 / 285 and no trend is claimed.** The mechanism is measurable and it is not a new disclosure: the private workshop submodule went from **53 to 290 tracked files in one commit** (5b611f9, 2026-09-01T21:02:46+02:00, 247 files changed, 97,035 insertions). This gate indexes tracked files only. The content did not become newly *disclosed*; it became newly *visible to the instrument*.

**12.2 · The name class — 57 rows, 7 digests, 0 people, and route (a) is not merely clean, it is empty**

Method as §10.3: the gate’s own `h()` digest re-implemented locally and each digest resolved against the public `file:line` it was reported at, by rebuilding that line’s capitalised 2- and 3-token runs with the gate’s own emitter (`shingle.awk`, extracted from the script and run unmodified). **No name and no matched token run is written into this document.**

**All 26 distinct (public file, line, digest) triples resolved — 57 of 57 rows, nothing left undetermined — and the 7 digests map to 7 distinct keys with no collision.**

**Derivation route, which was the question that classifies most of them: route (b) contributed 57 of 57. Route (a) contributed 0.** That is a stronger statement than §10’s, and it was measured rather than inferred from the source column: the git identities of the three private repositories (`ai_interviewing`, `monetization`, `workshop`) number **4**, the identities of the ten in-scope public repositories number **9**, and the set difference is **0**. Route (a) currently has **no candidates at all** on this tree — every person who has ever committed to a private repository here also commits to a public one under the same identity, so the subtraction empties it. Route (a) is **inoperative, not exonerating**, and that distinction matters for §12.6.

| Digest   | Rows | What it resolves to                                  | Where                                                         |
|----------|------|------------------------------------------------------|---------------------------------------------------------------|
| 04bc71a2 | 35   | a machine-learning model-hub <b>brand</b> , 2 tokens | specs/.../research/transcription.md ×5 lines                  |
| 0d3cb5ee | 12   | two <b>LLM-vendor brands</b>                         | <code>_content*/sites/vasic-digital.md ×11, _analysis/</code> |

| Digest   | Rows | What it resolves to                                                                                | Where                                                                       |
|----------|------|----------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------|
| 4411c8a8 | 5    | printed adjacently in a provider enumeration<br>a generic <b>document-type heading</b> , on line 1 | content-briefs/_TECH-STACK.md<br>design-toolkit/knowledge/platforms/*.md ×5 |
| 1fd9ab04 | 2    | an <b>HTTP response-header</b> name                                                                | docs/workshop-curriculum/RECON.md:540                                       |
| 2157bf5e | 1    | two <b>model-tier names</b> printed adjacently                                                     | _analysis/top20/cafcline.readme.txt:160                                     |
| 41735ecf | 1    | three <b>vector-database product names</b> , 3-token form                                          | submodules/RAG/README.md:426                                                |
| 4f8d043f | 1    | two of the same, 2-token form                                                                      | submodules/RAG/README.md:426                                                |

**Seven of seven are products, brands, protocol tokens or generic headings. Not one is a person. Zero redactions.** Every one is the separator-folding false positive the gate's own header documents at filter 3c — the detector is behaving as designed and its output is correctly red; what it found in this class is not a disclosure.

**The most sensitive private directory in this fleet produced five rows and they are all the same brand.** workshop/chapters/ — the recordings and the third party's notes PDF — is the private source of exactly 5 of the 4,249 matches, **all in the name class, all digest 04bc71a2, and zero in prose or short.** The private-side source path is that directory only because the brand also occurs there; the matched text is a vendor name in a table of model provenances on the public side.

### 12.3 · An eighth digest exists and the allow-list is hiding it — checked, and it is correct to

Re-run with `--allow <empty file>` (a command-line flag; `.content-boundary-allow` was not edited): **8,434 rows — prose 8,043, short 329, name 62**. The declared exemptions therefore suppress 4,185 rows, attributable in full to three pairs and **no others**: 3,893  
`ai_interviewing/docs/*` → `submodules/constitution/*`, 176  
`ai_interviewing/platform/content/*` → `submodules/constitution/*`, 116  
`* → docs/constitution-adoption/propagation/*`. The four §11.4.157 carrier-lockstep pairs pardoned **zero** rows this run.

**Exactly one name digest is suppressed by the allow-list, five rows, and it is the only row in the whole class that names a real human being.** It is a **published methodology author** — the originator of a well-known user-story quality mnemonic — **cited by name in the PUBLIC constitution corpus**, and reported at five PDF renders of that corpus. The private side is an interview-preparation note that quotes the public corpus. Direction measured, not assumed: `submodules/constitution/Constitution.md` first committed **2026-05-14**, its PDF render **2026-05-19**, the private note **2026-08-14** — the public source predates the private copy by three months. A scholarly attribution in the repository that is itself the source is not a disclosure of private material, and the exemption pair describes that flow correctly. **This is the one place where the allow-list touches the name class, it was checked rather than trusted, and it holds.**

### 12.4 · The prose and short classes — 4,192 rows, copy direction measured for every one

Not sampled. **Every row** was dated: the first-commit timestamp of the private file in its own repository against the first-commit timestamp of the public file in its own repository, for all 306 files involved. **Every one of the 306 resolved; none was left undetermined.**

| Disposition                                                                                       | Rows         | Share         |
|---------------------------------------------------------------------------------------------------|--------------|---------------|
| <b>PUBLIC IS THE ORIGINAL —</b><br>the public file<br>was committed<br>before the<br>private file | <b>4,112</b> | <b>98.1 %</b> |

| Disposition                                                                             | Rows     | Share      |
|-----------------------------------------------------------------------------------------|----------|------------|
| existed in its repository<br>private file committed first<br>— carried forward to §12.5 | 80       | 1.9 %      |
| <b>REAL DISCLOSURE</b>                                                                  | <b>0</b> | <b>0 %</b> |

By destination cluster, with the private-first count in each:

| Rows  | Cluster                                                                                                                                          | Private-first |

| 32   | the public<br>constitution<br>corpus                                                 | 0             |
| 88   | remainder,<br>spread thinly<br>over other public<br>submodules and<br>two root files | 0             |

**The single largest cluster is a private copy of code that was already public, and the private repository says so itself.** that directory carries a README whose title line declares the contents staged-but-unadopted candidates for contribution to an owned submodule, and it records a catalogue survey under §11.4.74 clause 4. (Described, not quoted — an earlier draft of this paragraph reproduced that title line verbatim and **the gate immediately reported two new short-class rows against this file.** The self-reference guard at the foot of this document is not theoretical; it fired within one run.) The public submodules/RAG/pkg/grounding/\*.go were committed at **2026-09-01T11:24:47**; the private staging copies at **2026-09-01T21:02:46** — the public files predate them by **9 h 38 m**, and the two versions have since diverged (64–212 differing lines), which is the shape of a fork of a published file, not of a leak. Same pattern for submodules/LLMProvider/scripts/lib/anchor.py: public **17:50:52**, private **21:02:46**.

**The second largest is a specification and its implementation, in that order.** specs/001-.../contracts/\*.md, tasks.md and research/\* were committed **2026-09-01T06:47:32 and 07:51:44**; the entire private

workshop/platform/\*\* tree entered git in one commit at **21:02:46**, 13 hours later. The public spec is the original; the implementation reproduces its wording. Redacting any of it would delete the plan to hide the plan.

**design-system/learning-kit/kit-tokens.css is byte-identical to its private counterpart and that is the design.** The public file was first committed **2026-08-13**, the private frontend copy on **2026-09-01**; .content-boundary-allow already declares the toolkit→design-system publication path for the neighbouring case.

**Website copy is public-first by weeks to months**, reconfirming \$10.7 on a larger set — e.g. milosvasic.ru/\_article\_src/en/helix-agent.md **2026-06-25** against workshop/curriculum/chapter-01/exercise-01.md **2026-09-01**, a gap of **68 days**.

**The transcript file is not the problem it looks like.** workshop/curriculum/chapter-01/transcript.md is the private source of exactly 2 of the 4,249 rows, both short-class, and both are the same generic navigational heading that any document may carry. **No transcript content reaches any public file.** monetization contributes **0** rows of any class.

## 12.5 · The 80 private-first rows, re-measured at the level of the text itself

File-level dating is a bound on when text entered a *repository*, not on when it was *written*, and it mis-scores the case where a NEW public file quotes text that was already public elsewhere. All 25 distinct (public file, line) pairs behind the 80 rows were therefore re-measured with `git log -S` over the line's own text, in both fleets:

- **24 of 25 are public-first or public-only at the text level.** 22 rows are the operator's own `usage()` boilerplate comment — the \$9.2 Class N1 finding, a code idiom repeated across his own scripts, carrying no subject matter at all. The rest are gate vocabulary whose public wording does not occur verbatim in any private repository.
- **1 of 25 is genuinely private-first**, and it is a three-minute gap inside one authoring session: a machine-generated **remedy string** telling an operator to install a common video-tooling dependency, emitted by a private HTTP endpoint and quoted in `scripts/verify-remedy-executability.sh` and `docs/check-registry.md` as that gate's worked example. Private **21:02:46** → public **21:06:00**. **Judged NOT a disclosure and left standing:** the dependency it names was

already public in specs/.../pipeline-cli.md at **06:47:32** that morning, fourteen hours earlier; the endpoint's own shape is published in specs/.../contracts/http-api.md; and the string carries no curriculum text, no participant, no personal data and no credential. The larger 48-row cluster in the same file scored private-first only by file date — its remedy text first appears in the **public** umbrella at **07:51:44**, thirteen hours before the private commit.

## 12.6 · Two independent checks that do not rely on the gate's own exonerations

A gate that clears something is not evidence that the something is absent. Both checks below bypass the gate entirely.

1. **The third party's given name — the identifier §11 redacted — is measured absent.** Derived programmatically from the private artefact's own path (never typed, never written down) and searched as a whole word across **every tracked file of all ten in-scope public repositories**, and separately across their tracked **paths**, and separately across this root's untracked working-tree files: **0 occurrences, everywhere**. §11.3's redaction holds in the working tree.
2. **No personal email address crosses the boundary.** 8 addresses occur in the private repositories, 252 in the public ones, **6 in both** — and all six are machine addresses: four `git@...` SSH remotes for the forge hosts, one package-author address inside a lockfile, one systemd unit address. None is a personal contact for anybody.

## 12.7 · What was deliberately left matching, and why

**Everything.** All 4,249 rows still appear in every run. Nothing was allow-listed, nothing was narrowed, no threshold was moved. Adding an exemption to reach `rc=0` here would assert boundary flows that do not exist and would have to claim, falsely, that a triage found something it resolved. **A red gate with a true reason beats a green one with a false reason**, and this gate's reason is true: 4,249 verbatim overlaps really do exist between these corpora. What this wave establishes is that **not one of them moves private material into public view** — 98.1 % because the public file is provably the original, and the remaining 1.9 % because the text is shared engineering vocabulary, machine-generated status strings, or by-design propagation.

A reader who disagrees with any disposition can re-derive it: the digests from §12.2's method, the copy directions from `git log --diff-filter=A --format=%at` and `git log -S`, the allow-list attribution from a `--allow <empty file>` run.

## 12.8 · What this wave did NOT do, and one new forward risk

**It changed nothing about §3, §8B or §11.4.** History still carries the wave-1 and wave-2 material; the GitHub Support purge is still unsent; the conversation with the third party is still the substantive remedy and is still the operator's to have. **No history rewrite was performed or prepared in this wave**, and none is implied by it — this wave found nothing that would need one. Were a third ever required, what it would have to cover is unchanged and is already written down at §8A.7 and §11.6: the four commits orphaned on 2026-09-01, the eight orphaned on 2026-09-02, and the 63ac4df32e5f... → 16cd4ba847de... mapping.

**New, and it is a forward risk rather than a finding:** two paths at this root are **untracked**, so the gate does not scan them and this wave's verdict says nothing about them — a session-audit document and an in-flight specs/002-... planning set, the latter of which does reference private repository paths. The commit wrapper runs `git add ..` **They enter scope the moment they are committed, and they must be swept then**, exactly as §10.9 warned about this file — which is now itself tracked, is now a scanned public destination, and already contributes one short-class row of ordinary English. §12 above is written descriptively for that reason.

## 13 · A SECOND, SEPARATE INSTANCE — a different person, a path component, no rewrite (2026-09-02)

Status: WORKING TREE REDACTED, UNCOMMITTED. NO HISTORY REWRITE — that is the operator's decision, taken explicitly. This is **not** a sixth wave of the incident recorded above. It is a **separate instance** of the same rule being broken: a different subject, a different source, a different route into the tree, and a different disposition. It is written into this file because

this file is where this repository keeps its boundary failures — not because the two are the same event. The name is **not written anywhere in this document**, and must not be.

### 13.1 · Why this is a separate instance and not another wave

§1–§12 concern exactly **one** person: the non-operator **participant** in the 2026-08-27 recording. This instance concerns a **different** person, referred to here only as **THIRD-PARTY-B** — the label assigned by the private review at workshop/docs/redaction-review-chapter-01.md §0. He is **not a party to that recording**. He is a person *talked about* in it. Nothing in §1–§12 is about him; nothing in §13 is about the participant.

That distinction was **measured**, not taken on the labels’ word. Five probes were derived inside a single process from workshop/curriculum/chapter-01/transcript.words.json, at the exact word indices the private review’s §3 table records, and none was ever typed:

| Check                                                                                              | How                                                                 | Result                                                  |
|----------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|---------------------------------------------------------|
| The participant’s probe ( <b>P1</b> ) and THIRD-PARTY-B’s probe ( <b>P2</b> ) are different tokens | in-process comparison of the two derived strings                    | $P1 == P2 \rightarrow$ <b>False</b> (4 characters vs 6) |
| P1 is the identifier carried by the recording’s own filename — i.e. the one §11 redacted           | whole-token split of all <b>40</b> entries of workshop/chapters/01/ | <b>P1 present, P2 absent</b>                            |

So THIRD-PARTY-B’s name never had the filename route §11 dealt with. It reached the public tree by an entirely different one, described next. Conversely, P1 returning **0** in §13.4 below is an independent re-confirmation that §11’s redaction still holds at the tip.

### 13.2 · What crossed, and where

|         |                                                                     |
|---------|---------------------------------------------------------------------|
| File    | docs/setup-agents-wizard/LUMEN-STORE-INVENTORY.md                   |
| Lines   | <b>99</b> and <b>157</b>                                            |
| Context | line 99 is rank 8 of the §3 “20 largest indexes” table; line 157 is |

|       |                                                                                                                 |
|-------|-----------------------------------------------------------------------------------------------------------------|
|       | the same store in the §5 “ <i>LIVE indexes (keep)</i> ” table. Both rows describe index dir<br>6ea66d6d87cbf1e9 |
| What  | an <b>absolute filesystem path</b><br><b>whose final component is THIRD</b><br><b>-PARTY-B’s given name</b>     |
| Class | <b>D3</b> — a direct personal identifier<br>— with an aggravating factor                                        |

---

The aggravating factor is the **parent** directory, which denotes work assignments. The disclosure is therefore not a bare given name; it is a given name **plus an implied working relationship**.

**The route is new and worth naming.** Neither line quotes anything. Nothing was copied out of the private transcript into this file: the path was captured from a live read-only inventory of the Lumen index store, and the *host’s own directory layout* carried the name. docs/content-boundary.md describes the leak vector as quotation — “*copying what is inside it*” — and this one is not a quotation, it is a **filesystem listing**. A document can therefore disclose a private fact it never read.

Both lines were byte-identical at HEAD, and HEAD is contained in origin/main — measured in the private review §7 with `git grep ... HEAD` (2 hits) and `git branch -r --contains HEAD (origin/main)`. **It is already public.**

### 13.3 · The redaction — 2 substitutions, one form, containment only

| Before                                            | After                                    |
|---------------------------------------------------|------------------------------------------|
| .../DATA4TB/Projects/assignments/<br><given name> | .../DATA4TB/Projects/<br>assignments/... |

---

One token is removed. The absolute prefix, the parent directory, the index-dir hash, the size, the file and chunk counts and both timestamps stay **verbatim**, so both tables keep their meaning and their alignment: a reader still learns that store 6ea66d6d87cbf1e9 indexes an assignment project of 294 files and 3 208 chunks, 13.0 MB, on the same Projects root as every other row.

Two choices are stated rather than left implicit:

- **The prefix was deliberately NOT made portable.** Fourteen other rows of these same two tables carry the identical `/run/media/`

<user>/DATA4TB/Projects/... prefix (twenty across the file), and it is the repository owner’s own host path, already public across this fleet. Rewriting it on two rows only would break the tables’ internal consistency and buy no privacy; rewriting it on all of them would be exactly the widening a containment pass must not do.

- **The form is this repository’s house elision** ..., the same one §11.3 chose, for the same stated reason — “*a redaction that destroys the finding is a failed redaction*”. Each of the two tables now carries a short **Redaction** note directly beneath it, so the ... reads as a deliberate elision and never as a truncated path; both point back here.

The substitution was applied by a script that **derives the token from the file’s own text at run time** and never contains it. There is no rules file, no allow-list, and no artifact of this instance that holds the name — nothing was written to a scratch file, and nothing was committed.

## 13.4 • Verification — run-time-derived probes, counts only

Scope is the **public umbrella**: `git grep` at this root, which does not descend into submodules, plus a `grep` over every untracked, non-ignored path. Matching was case-**insensitive** and whole-word (`git grep -I -n -i -w`).

| Probe | Review’s label | Tracked, before                              | Tracked, after | Untracked, after |
|-------|----------------|----------------------------------------------|----------------|------------------|
| P1    | PARTICIPANT-A  | 0                                            | 0              | 0                |
| P2    | THIRD-PARTY-B  | 2 — .../LUMEN-STORE-INVENTORY.md : 99, : 157 | 0              | 0                |
| P3    | THIRD-PARTY-C  | 0                                            | 0              | 0                |
| P4    | THIRD-PARTY-D  | 0                                            | 0              | 0                |
| P5    | ORG-1          | 0                                            | 0              | 0                |

The four zero rows are **actual measured empty results**, not unchecked assumptions, and they are the finding that matters as much as the hit: **exactly one name crossed**. The private review reached the same conclusion independently as its sweep **S9**; this is a second, later measurement of it, taken after the redaction.

The *identity* of the disclosure was measured too, not inferred from the review: the final path component at LUMEN-STORE-INVENTORY.md:99 was compared, lowercased, against P2 and found **equal**.

Two boundaries, stated plainly:

- **P2 is still 2 at HEAD**, and this change does not move that. `git grep -I -n -i -w -e <derived> HEAD` returns the same two lines after the edit that it returned before it. That is the whole of §13.6.
- `git grep` at this root does not descend into submodules, so these zeroes say **nothing** about the private workshop, `ai_interviewing` or `monetization` modules — where, for THIRD-PARTY-B, the name legitimately remains. Private-to-private is not publication.

### 13.5 · Why no gate caught it — the audit built to find absolute paths never looks in docs/

`scripts/audit-hardcoded-paths.sh` exists precisely to find absolute host paths in tracked files, and its own `PATTERN` matches these two lines exactly. It never saw them, because its `SKIP` filter removes `docs/` from the file list **before** the pattern is ever applied:

```
scripts/audit-hardcoded-paths.sh:328
  PATTERN=' (/Volumes/|/Users/[A-Za-z]|/home/[A-Za-z][A-Za-z0-9_.-]*)*/|/run/media/[A-Za-z]|/mnt/[A-Za-z][A-Za-z0-9_.-]*)/)'
scripts/audit-hardcoded-paths.sh:333
  SKIP='^(docs/|_content|_analysis|_tests/evidence/|\.test-evidence/|\.superpowers/|\.ashlrcode/|MANUAL-STEPS\.md)'
```

Measured at this root, 2026-09-02:

| Question                                 | Command                                                                                                                | Result   |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------|----------|
| Is the file tracked?                     | <code>git ls-files \</code><br><code>grep -cx &lt;path&gt;</code>                                                      | <b>1</b> |
| Does it survive the audit's SKIP filter? | <code>git ls-files \</code><br><code>grep -vE "\$SKIP"</code><br><code>\  grep -cx</code><br><code>&lt;path&gt;</code> | <b>0</b> |

| Question                                                          | Command                                                                       | Result |
|-------------------------------------------------------------------|-------------------------------------------------------------------------------|--------|
| How many of this repository's docs/ files does the audit scan?    | git ls-files \\<br>grep -vE "\$SKIP"<br>\  grep -c<br>'^docs/ '               |        |
| Do the two disclosed lines at HEAD match the audit's own PATTERN? | git show<br>HEAD:<path> \\<br>sed -n '99p;157p'<br>\  grep -cE<br>"\$PATTERN" | 2 of 2 |

The detector was right and the **scope** was wrong. **A blind instrument reports PASS** — the same sentence this repository's carriers already apply to gate E and to the two audits, now in a third place. Re-measured 2026-09-02, bash scripts/audit-hardcoded-paths.sh exits **0** and prints “ *no machine-specific hardcoded paths (9 file(s) explicitly allowed)*” — a green it returns while being structurally incapable of seeing either of the two lines this section is about. That 0 was never evidence about docs/.

**No gate was edited in this instance and the SKIP list was not touched.** Removing docs/ from it is a real change with real consequences — all **59** tracked docs/ files would enter scope at once, and this repository's documentation quotes host paths deliberately and constantly — and it belongs to whoever owns scripts/, not to a containment pass. It is recorded here as an **open finding**, not as a fix.

**The other instrument is NOT blind in the same way, and that distinction matters.** scripts/verify-content-boundary.sh was run at this root on 2026-09-02, after the redaction:

| Measurement                                            | Result                                                                                                               |
|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| Exit                                                   | <b>1</b> — LEAK – 10564 surviving match(es) (prose 10235, short 272, name 57); 0 row(s) also could not be determined |
| Distinct public docs/**/*.md files named in its output | <b>84</b>                                                                                                            |
| Distinct docs/setup-agents-wizard/ files named         | <b>10</b> of the directory's 20                                                                                      |
| Times it names LUMEN-STORE-INVENTORY.md                | <b>0</b>                                                                                                             |

So docs/ is squarely **inside** this gate's scope — it reads the very directory the disclosure lived in, and reports on ten of its files. Its silence on LUMEN-STORE-INVENTORY.md is therefore **not** a scope failure of the kind §13.5 documents for audit-hardcoded-paths.sh.

Honest boundary (§11.4.6), and it is a real one: **that run happened AFTER the redaction, so it is not an A/B and it establishes nothing about what the gate would have reported before.** No pre-redaction run of this gate exists for these two lines, and none was manufactured — deliberately re-introducing a live disclosure into the working tree to obtain a cleaner measurement would be a worse act than the missing datum. Whether a single given name inside a filesystem path is a shape this gate's name and prose classes can express is **not** established here and must not be recorded as though it were. The 10564 figure is likewise a dated observation of a moving detector against a moving fleet; it is not comparable to the 4,249 of §12 or to any earlier count, and no trend should be read into the three.

### 13.6 · Containment, not remedy — and the operator decided against a rewrite

**Everything §3 says about the first instance is true here, with the same force.**

1. The working tree is redacted. **The commits are not.**
2. The name is in the history of a **public** remote, and in **every clone, fork, mirror and provider cache already taken.** History is not editable after a push.
3. Whether that history has been cloned, scraped, cached or indexed is **UNVERIFIED** and, for most of those channels, unverifiable from here.
4. After this change lands, the name is still reachable by anyone with a clone at `git show HEAD:docs/setup-agents-wizard/LUMEN-STORE-INVENTORY.md`.

**The disposition is containment: no history rewrite, no force-push, and no push at all.** The redaction was left uncommitted in the working tree for the operator. This is a deliberate decision and it differs from §8B and §11.4, where a rewrite was authorized and executed.

Recorded honestly rather than dressed up: unlike §11.1, **no verbatim wording of that decision was captured** by the agent that performed this work. It was relayed to it as *operator decision 17, 2026-09-02 — containment*, and is written down as exactly that. §11.1's rule stands

and is not weakened by this paragraph: an authorization that cannot be quoted is recorded as a relayed instruction, never promoted into a quotation it never had.

That decision is defensible and it is **not** this document’s to second-guess. What this document must not allow is the decision being remembered as a closure. **It is not one.** The substantive remedy for a disclosure about a person is the same one the status block at the head of this file records as still outstanding for the first instance: **telling the person.** That has not been done for THIRD-PARTY-B either, and it is the operator’s to do.

**Do not mark this closed, and do not read any gate result below as bearing on it.** The gate table that follows measures the *tip of the tree*. This section is about what is behind it.

---

## Gate results

Recorded at the end, not the top, so that they are read as evidence and not as a verdict on the incident. **The incident is not closed. History still carries the content.**

Measured 2026-09-01, working tree, nothing committed.

| Gate                                                | Exit | Result                                                                                                                                                       |

## Wave 4 — measured 2026-09-02, after the redaction, the rewrite and the push

Every one of these was run against the tree that is now on refs/heads/main (2d629e93e92a...). Exit codes are reported verbatim, including the one that is red.

| Instrument                                                                  | Exit     | Result                      |

|------------------------------------|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| scripts/verify-content-boundary.sh | 1    | LEAK — <b>4249</b><br>surviving matches (prose <b>4002</b> , short <b>190</b> , name <b>57</b> ), 0 undetermined; 9 declared exemption pairs pardoning 4187 matches; 107 files not indexed (over the 524,288-byte cap or machine-generated).<br><b>RED BY DESIGN and PRE-EXISTING — do not force it green.</b> |

**Read the content-boundary row carefully; it is not an A/B for this wave.** The earlier figures in this document (377 → 232 → 203 → 367) and the **285** recorded in CONTINUATION.md are **not comparable** to 4249: the fleet grew from 9 declared gitlinks to **13** (submodules/LLMProvider, submodules/RAG, submodules/passage, submodules/verdict joined), and this gate scans submodule interiors, so the corpus it indexes is a different corpus. **No before/after claim is made for wave 4 on this gate.** What *can* be said, and is bounded and checkable: this wave's edits **removed** 14 occurrences of a name from history and **added** only four short "Redaction" notes and this document's §11, none of which contains a personal name. Nothing here can have created a name-class row.

**The name 57 figure is the one to look at, and it is unfinished business.** §10 assessed **125** name-class candidates and judged all 125 false positives — at a measurement taken before the fleet grew. The current 57 rows have **not** been individually re-adjudicated by this wave, and this wave does not claim they have been. That is a **known open item**, not a pass.

**Wave 5 — measured 2026-09-02, triage only, no edit to any scanned public file**

**The tree moved under the instrument during this wave, and that is stated rather than smoothed over.** Another agent committed inside the private workshop submodule and modified specs/001-.../tasks.md at

this root while the triage was in progress. The A/B above is clean because *before* and *after* were taken either side of one edit to one file; the later re-verification is not an A/B for this wave and is not offered as one. **Any figure in §12 is a dated observation of the corpus as it stood at commit e432703 plus workshop@5b611f9. Re-derive before relying on it.**

**A second null A/B, and for the same reason as wave 3.** The name class is now fully adjudicated — 57 of 57 rows resolved, 7 of 7 digests classified, **0 people, 0 redactions** — and the prose and short classes are adjudicated for the first time, by dating **every** row rather than sampling: **4,112 of 4,192 are public-first, 80 are not, and 0 are disclosures.** The name 57 figure that wave 4 recorded as “*unfinished business ... a known open item, not a pass*” is **closed as a finding**; it remains open as a *red gate*, which is the correct resting state.

**.content-boundary-allow was not touched, no entry was added, and scripts/verify-content-boundary.sh was not edited.** The only file this wave changed is this one.

### **Wave 3 is a null A/B, and that is the correct outcome**

The before and after runs are byte-identical in every class. **This is not a failed wave; it is a swept class with no disclosure in it.** All 125 name-class rows were resolved to their exact file:line, all 20 digests classified, and all 20 are products, brands, technologies, adjectives, headings or repository names — §10.4. Redacting any of them would have removed correct technical prose from live public pages to hide words that are not personal data.

**.content-boundary-allow was not touched, and no entry was added.** The gate exits 1 and should: the 242 prose/short rows are the Class N1/N2 judgements of §9.2, still visible on purpose, and the 125 name rows are visible for the same reason. A reader who disagrees with a disposition can re-derive it from §10.3 and overrule it.

**On the prose/short totals: 242 here against the 203 recorded at wave-2-after is NOT a regression this wave caused, and it is not claimed to be a clean comparison either.** Other agents were active in this tree between the two measurements — `git status` at the start of wave 3 showed 30+ modified tracked files, including governance carriers and several `scripts/*.sh` — and the private-side corpus and the gate’s derived exoneration sets move with them, exactly as “Read the content-boundary numbers carefully” describes for 377 → 232. **The**

**difference was not attributed, because attributing it would require re-deriving the wave-2 split, and that was not done.** Do not read it as a number this wave is responsible for.

**Wave 2 is a clean A/B, and the -29 is fully attributable**

Unlike the 377 → 232 comparison, nothing about the instrument’s input changed between the wave-2 before and after runs: same fleet (13 gitlinks, 3 private), same derived exoneration (897 path-mask shingles, 786 already-public shingles, 9 declared pairs, 4,043 pardoned), same 105 not-indexed files, 0 undetermined on both sides. **232 – 203 = 29, and all 29 are the Class R redactions of §9.3,** confirmed per file:

| Public file                                          | Before | After |
|------------------------------------------------------|--------|-------|
| docs/workshop-curriculum/RECON.md                    | 13     | 0     |
| specs/001-workshop-curriculum-platform/quickstart.md | 16     | 0     |

workshop as a private source went **16 → 0**. No other file’s count moved.

**The 203 that remain are deliberate, and exempting them would be the bluff**

**.content-boundary-allow was not touched, and no entry was added to force a green run.** The gate exits **1**, correctly, and the 203 surviving matches are the Class N1 (22) and Class N2 (181) rows of §9.2 — the operator’s own usage() boilerplate, and his own public-first product copy that the private interview-prep notes reproduce. They are **judged not to be disclosures, not suppressed**, so they still appear in every run, by design. A reader who disagrees with the judgement can see the evidence and overrule it.

**A red gate with a true reason beats a green gate with a false one.** Chasing rc=0 here would require either deleting live public website content or writing allow-list entries that assert a boundary flow which does not exist. Both are worse than the red. | scripts/verify-check-registry.sh | **0** | 23 PASS / 0 FAIL / 5 DEBT / 0 UNDET. **R5 passes** — verify-content-boundary.sh is now registered. The 5 DEBT rows are declared, not fixed, and print by design. | | scripts/audit-hardcoded-paths.sh | **0** | no machine-specific hardcoded paths (6 files explicitly allowed) |

## Read the content-boundary numbers carefully — 377 → 232 is not a clean A/B

**The instrument's input changed between the two runs, so the totals are not comparable and must not be reported as a 145-match improvement.** Another agent was concurrently building workshop/platform/\*\* — a Go backend and an Angular frontend — inside the **private** workshop submodule, and governance carriers changed under submodules/constitution/submodules/design-toolkit/. Both feed the private-side corpus the gate indexes, and its *derived* exoneration sets moved accordingly: already-public 793 → 786 shingles, declared exemptions 5,055 → 4,043 matches pardoned. That is why files this work never touched — \_analysis/design-research/INCORPORATION-PLAN.md (55 → 0), CATALOG.md (19 → 0), docs/constitution-adoption/INVENTORY.md (12 → 0) and others, 116 matches in total — changed count on their own.

**The attributable figures are per-source, and they are unambiguous:**

- Matches whose private source is the notes PDF: **29 → 0**. Every one is gone.
- docs/workshop-curriculum/RECON.md: **42 → 13**, a drop of **exactly 29**. The residual 13 are ai\_interviewing-sourced (:423, :475, :477, :504) and belong to the separate, out-of-scope incident in §6.
- specs/.../research/transcription.md: **0 both times** — the gate never saw this file's leak, which is F2.

**The gate still exits 1, and that is correct.** 232 real matches remain, from design-toolkit/ and ai\_interviewing/. **Nobody should exempt them to get a green run.** .content-boundary-allow says so itself: those rows are *“left visible so a human decides rather than a glob.”*

The stronger evidence for this work's own completeness is §7's independent sweep at a **six**-word window — stricter than the gate — which found **zero** prose overlap remaining in either redacted file.

---

**Do not close this incident on the strength of the two exit-0 gates above.** They say the registry is consistent and no hardcoded paths were introduced. They say nothing about the disclosure, which is still live in 63ac4df on a public remote.

§13 — measured 2026-09-02, after the redaction. NOT an A/B, and not a wave.

Kept apart from the wave rows above on purpose: every pair up there is a before/after of the same tree, and this is not one. §13 is a **separate instance**, and only its *after* was measured.

| Instrument                                       | Exit | Result                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|------------|------|-----------------------|
|            |      | unchanged. See §13.4. |

**Neither row licenses a conclusion about what the content-boundary gate would have reported before the redaction.** No pre-redaction run exists for these two lines and none was manufactured. The 10564 is a dated observation of a moving detector against a moving fleet — **not** comparable to the 4249 of wave 4 or the 367 of wave 3, and no trend may be read across the three.

**Self-reference guard.** This document deliberately DESCRIBES the false-positive classes rather than quoting them. Writing a capitalised two-token pair here in plain text would make this file its own name-class source the moment it is tracked — and the project commit wrapper runs `git add ..` Re-derive examples from the gate, never from here.
